(Corals from E Kalimantan outcrops contain 79 genera and 234 species. Three different coral assemblages in small patch reefs, developed under influence of high siliciclastic input from Mahakam Delta. Platy coral assemblages (Porites, Leptoseris, etc.) common until Serravallian, branching corals became dominant in Tortonian. By Late Tortonian massive coral assemblages dominated, similar to modern-style coral framework)

Santodomingo, N., C.C. Wallace & K.G. Johnson (2015)- Fossils reveal a high diversity of the staghorn coral genera *Acropora* and *Isopora* (Scleractinia: Acroporidae) in the Neogene of Indonesia. Zoological J. Linnean Society 175, 4, p. 677-763.
(online at: https://academic.oup.com/zoolinnean/article/175/4/677/2449809)
(Extensive collections of Miocene corals from E Kalimantan, Indonesia, with 31 species of Acropora and 2 of Isopora, in E Miocene (max. age 18-20 Ma). 12 extant species already present in E Miocene. Most corals associated with shallow turbid habitats)

Santoso, B. (2009)- Geologic factors controlling mineral content in selected Tertiary coals- southern Kalimantan. Indonesian Mining J. 12, 2, p. 67-74.
(online at: http://jurnal.tekmira.esdm.go.id/index.php/imj/article/view/565/427)
(In Asem-Asem basin average mineral content of Miocene coals (3.9%) lower than Eocene coals (6.7%). Miocene coals bright lithotypes/ vitrinite-rich coal with fewer clay partings; Eocene coals dull lithotypes/vitrinite-poor)

Santoso, B. (2011)- Geologic aspects controlling maceral and mineral matter content of Satui coals- South Kalimantan. Indonesian Mining J. 14, 2, p. 63-73.
(online at: http://jurnal.tekmira.esdm.go.id/index.php/imj/article/view/494/358)
(Coals in Asem-Asem Basin, SE Kalimantan, in Eocene Tanjung and M Miocene Warukin Fms. Eocene(?) coals from Satui area dominated by bright-banded and banded types. Vitrinite and liptinite dominant macerals, minor inertinite Mineral content relatively high. Brighter coal more vitrinite-rich. Vitrinite reflectance 0.48-0.54%)

Tectonics and sedimentation of Indonesia, FOSI-IAGI-ITB Regional Seminar to commemorate 50th anniversary of Van Bemmelen's Geology of Indonesia, Bandung 1999, p. 62. *(Abstract only)*
(Summary of gravity field of Kutei Basin and surrounding areas. Onshore Bouguer anomalies generally from +10 to +50 mGal; in Balikpapan area depocenter ~75 mGal. Assuming 9000m of sediment and underlying continental crust, anomalies here should be ~ -115 mGal. One possible explanation is rise in Moho)

Sardjono, S. & L. Rotinsulu (1992)- The hydrocarbon generation and trapping mechanism within the northern part of Barito Basin, South Kalimantan. Proc. 21st Ann. Conv. Indon. Assoc. Geol. (IAGI), Yogyakarta, 1, p. 131-145.
(In NE Barito basin hydrocarbons sourced from two intervals: Eocene Tanjung Fm (lacustrine oil type) and Miocene Lower Warukin Fm (fluviodeltaic oil type). First hydrocarbon generation in M Miocene from Tanjung source; from Warukin source in Plio-Pleistocene)

Satyana, A.H. (1995)- Paleogene unconformities in the Barito Basin, Southeast Kalimantan: a concept for the solution of the "Barito dilemma" and a key to the search for Paleogene structures. Proc. 24th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 263-275.
(Barito basin only 4 commercial discoveries, all in NE part of basin. Multiple unconformities and young inversion. Suggests fields are preserved paleo-traps not affected by young structuring)

Satyana, A.H. (2010)- Geodynamic origins of Kalimantan sedimentary basins. Proc. 39th Ann. Conv. Indon. Assoc. Geol. (IAGI), Lombok 2010, 8p.
(Sedimentary basins of Kalimantan prolific for petroleum and coal deposits. Paleogene geologic evolution of SE Asia strongly controlled by escape tectonics due to collision of India to Eurasia in M Eocene. Trans-Kalimantan Lupar-Adang-Paternoster strike slip fault, opening of Makassar Strait and opening of S China Sea responsible for formation of sedimentary basins in Kalimantan-Borneo)

Satyana, A.H. & E. Biantoro (1996)- Seismic stratigraphy of Eocene Beriun sands of West Bungalun, East Kalimantan, Indonesia: a contribution to the Palaeogene stratigraphical knowledge of the Kutai Basin. In: C.A. Caughey et al. (eds.) Proc. Int. Symp. Sequence Stratigraphy in SE Asia, Jakarta 1995, Indon. Petroleum Assoc. (IPA), p. 383-393.
(Kutei Basin up to 12,000m of sediments. E Eocene- E Oligocene generally transgressive sequences. Eocene NE Kutei W Bungalun area Beriun reservoir-quality sands equivalent to hydrocarbon-bearing Tanjung sands of Banto Basin. At least three seismic stratigraphic sequences. Deposition affected by growth faulting. Interpreted as fan delta deposits in extensional tectonic regime)

Satyana, A.H. & R. Idris (1996)- Chronology and intensity of Barito uplifts, Southeast Kalimantan: a geochemical constraint and windows of opportunity. Proc. 25th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, p. 207. *(Poster Abstract)*
(Barito Basin Paleogene mainly extensional deformation. Uplift and inversion of extensional structures starting in Miocene and continuous today. Five uplift events in Tertiary: M Eocene, E-M Oligocene, late Oligocene- E Miocene, M Miocene and Late Miocene- Pleistocene. First two uplift episodes interrupted Paleogene extension. Late Miocene- Pleistocene major uplift event (~1200m). Oligo- Miocene uplift relatively minor (~50m))

Satyana A.H., D. Nugroho & I. Surantoko (1999)- Tectonic controls on the hydrocarbon habitats of the Barito, Kutei and Tarakan Basins, Eastern Kalimantan, Indonesia: major dissimilarities in adjoining basins. J. Asian Earth Sci. 17, 1-2, p. 99-122.
(Barito, Kutei, and Tarakan Basins different Tertiary tectonic styles. Barito Basin initial transtension followed by transpression. NE structures increasingly imbricated towards Meratus Mts and involve basement. W and SE Barito Basin weakly deformed. Kutei Basin dominantly tight NNE-SSW trending anticlines, forming Samarinda Anticlinorium in E. Deformation less intense offshore. M Miocene- Recent growth suggested by thinning over structures. W basin area uplifted. Tarakan Basin NNE-SSW normal faults, formed on older NW-SE trending folds and normal to direction of sedimentary thickening, suggesting growth-faults. Onshore older N-S trending folds from collision of Central Range terranes to W of basin. Barito Basin fields in W-verging faulted anticlines. Tarakan Basin NW-SE anticlines with main producing pools in downthrown blocks of faults)

Satyana, A.H., M.E.M. Purwaningsih & M. Imron (2002)- Coal seams within Eocene Tanjung Formation of the Barito Basin, Southeast Kalimantan: sequence stratigraphic framework and geochemical constraints for source potential. Berita Sedimentologi (Indon. Forum Sedimentologi, FOSI) 17, p. 14-21, 26.
(Barito Basin M Eocene synrift- postrift Lower Tanjung Fm clastics 7 sequences. Coals in three sequences of postrift phase. Mostwidespread and thickest coal seams in transition between synrift- postrift phases. Coals deposited in paralic to upper deltaic settings in various systems tracts. Coals TOC 44-73%, hydrogen index (HI) 285-567 mgHC/gTOC and hydrogen to carbon ratio (H/C) of 0.87-1.18, showing coals are liptinitic and can generate oil. Carbon isotopes and biomarkers show Tanjung Fm coals sourced Tanjung field oil)

Satyana, A.H. & P.D. Silitonga (1993)- Thin-skinned tectonics and fault-propagation folds: new insights to the tectonic origin of Barito folds, South Kalimantan. Proc. 22nd Ann. Conv. Indon. Assoc. Geol. (IAGI), Bandung, 1, p. 282-291.
(Barito Basin foredeep at Meratus front with closely spaced folds-thrusts, formed in M Miocene and Plio-Pleistocene, all with high-angle reverse faults. Become increasingly imbricate towards Meratus Range. Strike slip faults cut older structures. Hydrocarbons known only from folds and paleo-highs in N end of foredeep.

Satyana, A.H. & P.D. Silitonga (1994)- Tectonic reversal in East Barito Basin, South Kalimantan: consideration of the types of inversion structures and petroleum system significance. Proc. 23rd Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, p. 57-74.
(E Barito basin Tertiary structural history characterized by tectonic reversal. Paleogene rifting with NW- SE trending horsts and grabens followed by WNW to ESE Neogene compression with inversion of Paleogene structures. Rift sedimentation resulted in E-M Eocene Lower Tanjung source rocks and reservoir sandstones. Late Eocene- E Oligocene U Tanjung Fm postrift shales effective seal. Inversion started in E-M Miocene (N Kalimantan and E Sulawesi collisions). Plio-Pleistocene inversion might create new traps or destroy previous accumulations and remigrate hydrocarbons. Tanjung Raya fields ideal hydrocarbon-trapping conditions)

Sawada, H., T. Matsuyama, Y. Konda, T. Ishiyama & T. Hashimura (2007)- Middle and Upper Miocene slope channel sandstone reservoir of Sadewa gas field, offshore Mahakam Delta, North Kutei Basin, East Kalimantan, Indonesia; modeling of channel sand body based on exploratory wells and 3D seismic. In: Proc. JAPT Symposium Exploration and exploitation in deep water, Sendai 2006, J. Japanese Assoc. Petroleum Technologists (Sekiyu Gijutsu Kyokaishi), 72, 1, p. 98-107.
(online at: www.jstage.jst.go.jp/article/japt/72/1/98/_pdf)

(In Japanese with English summary. Sadewa Field 2002 gas discovery on slope in 1000-2800' water off Mahakam delta. Cores of Sadewa reservoir exhibit episodic turbiditic deposition of reworked delta sediments. Slope channel sandstone reservoirs of Sadewa field detected as high-amplitude anomalies in 3D seismic data)

Sidi, F.H., H.C. Baskara, G.P. Allen & S.C. Lang (1998)- Controls on cyclic sequence architecture in the Middle Miocene paleo-Mahakam Delta system, Badak and Nilam fields, Kutai Basin, East Kalimantan, Indonesia. AAPG Int. Conf. Exhib. Abstracts, American Assoc. Petrol. Geol. (AAPG) Bull. 82, 10, p. 1966-1967.
(Badak and Nilam fields in M Miocene paleo-Mahakam fluvio-deltaic system. Productive horizons numerous isolated mouth bar and distributary channel sandstone reservoirs in basin with high subsidence rates and high sediment influx. High degree of cyclicity at three scales: (1) smallest (100-150') represent delta lobes, parasequences produced by autocyclic processes (2) Intermediate (800-1200') regressive-transgressive parasequence sets; (3) largest (6000-8000') associated with major basin-fill patterns due to progradation of shelf and slope. Larger-scale maximum flooding events cut across regional stratigraphic markers, indicating they are diachronous along depositional strike. Lateral variations in stacking patterns, controlled by migration of zones of sediment influx. Local tectonic effects tend to blur eustatic signatures in basin)

Sidi, F.H., S. Damayanti, H.C. Baskara & I. Turseno (1998)- Stratigraphy and geometry of deltaic reservoirs of the paleo-Mahakam system: an example from sequence stratigraphy study of Nilam gas field, Kutei Basin, East Kalimantan, Indonesia. In: C.A. Caughey & J.V.C. Howes (eds.) Proc. Conf. Gas habitats of SE Asia and Australasia, Jakarta 1998, Indon. Petroleum Assoc. (IPA), p. 179-185.

Sieffermann, G.R. (1990)- Origin of iron carbonate layers in Tertiary coastal sediments of central Kalimantan Province (Borneo), Indonesia. In: J. Parnell et al. (eds.) Sediment-hosted mineral deposits, Int. Assoc. Sedimentologists (IAS), Spec. Publ. 11, p. 139-145.
(Siderite layers 20-30cm thick in Miocene coal-bearing series reflect reprecitation of iron in (brackish) coastal plain zone)

Siemers, C.T., S. Sutiyono & S.K. Wiman (1992)- Description and reservoir characterization of a Late Miocene, delta-front coral-reef buildup, Serang Field, Offshore East Kalimantan, Indonesia. In: Carbonate rocks and reservoirs of Indonesia: a core workshop, Indon. Petroleum Assoc. (IPA), p. 5-1-5-27.
(Late Miocene in Serang Field dominated by fluvial/deltaic and shallow-marine siliciclastics. Also numerous carbonate units indicative of coral reef growth in delta-front, marine-shelf setting. The 80-6 Limestone (67'), includes 'Lower reef' (25'; platy corals in argillaceous matrix grading up to massive and branching coral fragments in mud matrix) and 'Upper reef' (42'; platy-coral-bearing wackestone, overlain by argillaceous coral rubble, porous 10' reef-core type coral rubble and 13' of non-porous, reworked mix). Reef overlain by shallow shelf- delta-front calcareous, shelly, silty shale. 80-6 Limestone represents cluster of buildups with lateral extent of >2.5 km and possibly up to10's of kms. Post-depositional degradation of reservoir quality. Extensive recrystallization of skeletal fragments (especially corals, molluscs) and carbonate mud matrix).

(N Kutai Sangatta delta (Balikpapan and Kampung Baru Fms) development started in E Miocene with at least two fluvial-deltaic parasequence sets prograding to E. Delta became larger in M-L Late Miocene as regional inversion and uplift took place at Kuching High to W of delta. >10 stacked fluvial- deltaic parasequence sets identified, all showing progradation to E)

Subekti, A., K.P. Laya, E. Guritno & M.N. Krisnayadi (2017)- Greater Bangkanai prospectivity: the application of full-tensor gravity and magnetic survey, onshore Central Kalimantan. Proc. 41st Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA17-361-G, 17p.
(Gravity-mag survey in upper Kutai Basin, in area with Kerendan and West Kerendan gas fields in Oligocene carbonates. NE-SW trending surface anticlines are mainly (M Miocene?) inversions of M-L Eocene extensional structures)

Subekti, A., H. Mustapha, E. Guritno, J. Smart, A. Susilo, B. Nugroho, W. Darmawan & M. Wilson (2015)- New insights into the Kerendan Field carbonate morphology Upper Kutai Basin, Central- East Kalimantan. Proc. 39th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA15-G-118, 16p.

(Late Oligocene Berai carbonate play in Upper Kutai Basin underexplored; Kerendan discovered by Unocal in 1982 is only hydrocarbon accumulation, in carbonate platform with two culminations with common gas-water contact. Oligocene carbonate built on NNE-SSW trending Paleogene horsts. Kerendan High created by inversion of rift faults. Kerendan Carbonate system not atoll rim carbonate with interior lagoon as previously interpreted, but open platform carbonate complex with partially developed rim in which platform, coral reefal buildups and carbonate sand aprons developed. Most porosity secondary, diagenetic)

Subroto, E.A. (2015)- The role of coaly materials as source rocks (conventional and unconventional) in the Kutai Basin, Indonesia. In: Hydrocarbons in the tropics: on the edge, Abstracts 32nd Ann. Mtg. Soc. Organic Petrology, Yogyakarta 2015, p. 123-128. *(Extended Abstract)*
(Five proven and potential types of petroleum source rocks identified in Kutai basin. Most oils tied to deltaic coaly shales. Coaly materials significant role in hydrocarbon generation, conventional and unconventional)

Subroto, E., A. Bachtiar & B. Istadi (2006)- Source rock characterisation in the Kutai Basin, East Kalimantan, Indonesia, based on biomarkers. Proc. Jakarta 2006 Int. Geosc. Conf. Exhib., Indon. Petroleum Assoc. (IPA), Jakarta06-PG-28, 4p.
(Analyses 73 crude oils and 86 rock samples from Kutai Basin. Based on biomarkers five source types: deltaic coaly shales, marine shales, mixed deltaic and marine shales, marine calcareous shales, and immature deltaic coaly sediments. 62 oils correlate to deltaic coaly shales, remaining 11 correlate to marine shales. No mixed sources detected in crude oils. Vitrinite reflectance data for some sediments appear to be suppressed)

Subroto, E.A., B.P. Muritno, Sukowitono, D. Noeradi & Djuhaeni (2005)- Petroleum geochemistry study in sequence stratigraphic framework in the Simenggaris Block, Tarakan basin, East Kalimantan, Indonesia. Proc. 30th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, IPA05-G-159, p. 421-432.
(Tarakan Basin Simenggaris Block 8 Oligocene-Pliocene sequences, with shales TOC between 0.65- 7%, indicating several may be hydrocarbon source. Almost all sequences contain some coals or carbonaceous materials. Only SB-2 and SB-1 (Naintupo Fm and older) reached optimal maturity. In deeper areas SB-5 to SB-3 (Meliat Fm) are in middle mature stage)

Sudarmono, A. Direza, H.B. Maulin & A. Wicaksono (2017)- Some new insights to tectonic and stratigraphic evolution of the Tarakan sub-basin, North East Kalimantan, Indonesia. Proc. 41st Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA17-722-G, 22p.
(Tarakan Basin with E-ward prograding fluvio-deltaic sedimentation since E Miocene, sourced from multiple feeder rivers (Sesayap, Sesanip and others). Deltaics at and E of Bunyu Island deposited on oceanic crust of Celebes Sea. Tarakan sub-basin bounded by left-lateral strike slip faults Sampoerna (in N; Celebes Sea transform fault?) and Maratua and Mangkalihat FZs (in S; continuation of Palu-Koro fault of Sulawesi?). Major tectonic event at end of Late Miocene (end of Santul Fm), which uplifted part of area E of Kucing High. Second major tectonic event in Pleistocene, forming present-day Bunyu, Tarakan and Ahus structures)

(online at: http://ro.uow.edu.au/theses/1405/)

(Melawi and Ketungau similar basins, separated by Paleocene-E Eocene Semitau High (composed of highly deformed turbiditic Selangkai Fm and U Cretaceous 'Boyan melange' tectonic breccia). Melawi Basin fill up to 7500m thick Eocene- Oligocene, gently folded, in 4 main units: (1) ?Late Eocene Ingar Fm outer shelf mudstone (typical Eocene palynomorphs, also common reworked U Cretaceous marine forams), sandstones derived from magmatic ar detritus from Schwaner Mts in S; (2) Late Eocene fluvial and marine Suwang Gp (Dangkan Sst, Silat Shale), with increasing quartz and decreasing volcanics of recycled orogen-type provenance;(3) Melawi Gp fluvial- lagoonal with Late Eocene Payak Fm/ Sepauk Sst and E Oligocene Tebidah Fm; (4) Oligocene fluvial Kapuas Gp, unconformably over Melawi Gp after E Oligocene minor folding. With Late Oligocene- E Miocene Sintang intrusives. Provenance from S and W in Ingar Fm, mainly from melange/ subduction complex in N in Suwang and Melawi Groups (recycled orogenic material from uplifted Late Cretaceous Boyan and Eocene Lubok Antu melanges?). With palynology analyses by B. Porthault of Elf-Aquitaine (later papers by Sutjipto under name Heryanto; JTvG))

Suwardji, A. Buhari, K. Kukuh & R. Prayitno (1994)- Low resistivity reservoir study: Sangatta field, Kalimantan. Proc. 23rd Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 2, p. 119-130.
(Identification of previously unrecognized low-resistivity oil reservoirs in Sangatta Field (1936 BPM discovery, developed by Pertamina in 1970's))

(Paleocurrent and provenance data from W flank of Meratus Mountains. Paleocurrents and sandstone provenance of Kiwa Member suggest N part of Meratus was uplifting in E Miocene. Paleocurrents from M-L Miocene Warukin Fm two distinct trends, first to ESE (present-day Meratus), second to WNW (i.e. away from Meratus; in channel sandstones in uppermost ~500m of formation. Switch in paleocurrents interpreted as recording Late Miocene early stage of uplift of S Meratus Mts)

Witts, D., L. Davies & R. Morley (2014)- Uplift of the Meratus Complex: sedimentology, biostratigraphy, provenance and structure. Proc. 38th Ann. Conv., Indon. Petroleum Assoc. (IPA), Jakarta, IPA14-G-082, 21p.
(SE Kalimantan Meratus Mts emerged diachronously in E Miocene in N, earlier than previously suggested, but in Late Miocene further S. Paleocurrents from Warukin Formation directed towards ESE (i.e. towards present-day Meratus) in lower part, to WNW (i.e. away from Meratus) in upper ~500m of formation (M-U Miocene Tapin Mb). Paleocurrents in E Miocene Kiwa Mb of Montalat Fm indicate sediment transport to NW (zircons age populations same as in Eocene Tanjung Fm, suggesting reworked Tanjung Fm from Meratus High?). Meratus Range probably elongate positive flower structure)

Witts, D., L. Davies, R.J. Morley & L. Anderson (2015)- Neogene deformation of East Kalimantan: a regional perspective. Proc. 39th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA15-G-246, 22p.
(Review of Adang Line, etc.)

Witts, D., R. Hall, R.J. Morley & M.K. BouDagher-Fadel (2011)- Stratigraphy and sediment provenance, Barito basin. Proc. 35th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA11-G-054, 18p.
(Revised Eocene- Miocene stratigraphy and depositional model for Barito basin surface sediments. M Eocene-E Oligocene Tanjung Fm clastics, minor limestones and coal deposited in fluvio-tidal coastal plain to marginal marine setting, sediment sourced from W and SW and mainly derived from metamorphic rocks. M-L Miocene Warukin Fm marginal marine to fluviodeltaic, sediment was being transported from W for oldest part, mainly derived from Schwaner Complex, lesser extent Rajang-Crocker Gp, partly from E for younger coal-bearing sequences (=Meratus Mts uplift?))

Witts, D., R. Hall, G. Nichols & R. Morley (2012)- A new depositional and provenance model for the Tanjung Formation, Barito Basin, SE Kalimantan, Indonesia. J. Asian Earth Sci. 56, p. 77-104.
(Tanjung Fm of Barito Basin deposited from late M Eocene- late Early Oligocene. Most of formation deposited in tidally-influenced coastal plain and estuarine setting, and sediment was transported by rivers flowing to N (NB: Witts et al. 2011 suggest Tanjung Fm from W and SW?; Heryanto & Panggabean 2004 suggested mainly from WNW; JTvG). Heavy minerals and zircon geochronology identified Schwaner Complex W Borneo, Karimunjawa Arch and S continuation of Meratus Complex in Java Sea as main sediment sources)

(Melinau Lst in NE Sarawak up to 7000' thick. Age based on larger foraminifera Late Eocene- E Miocene. One new genus, Wilfordia, three new species: Dictyoconus melinauensis, Neoalveolina inflata, and Wilfordia sarawakensis. Dictyoconus recorded for first time from Oligocene-age strata)

Adams, C.G. & R. Haak (1962)- The stratigraphical succession in the Batu Gading area, Middle Baram, North Sarawak. In: N.S. Haile, The geology and mineral resources of the Suai-Baram Area, North Sarawak, British Borneo Geol. Survey Memoir 13, p. 141-150.
(Along Middle Baram River in NE Sarawak ~120' N-dipping massive Late Eocene limestone unconformably on folded Late Cretaceous Kelalan/ Rajang Fm. Late Eocene with Tb larger forams Pellatispira, Discocyclina, Aktinocyclina, Nummulites javanus, etc. Overlain (with erosional surface/ E Oligocene hiatus) by 40' thick limestone breccia and bedded limestone with reworked Eocene larger forams and Heterostegina borneensis, Spiroclypeus, Eulepidina, Borelis pygmaeus and Miogypsinoides (Te1-4; interpreted as E Miocene, but should be latest Oligocene; JTvG). Overlain by earliest Miocene (N4-N5) calcareous shales with Globigerinoides, Globigerina binaiensis, G. dissimilis, G. ciperoensis)

Adams, C.G. & H.J.C. Kirk (1962)- The Madai-Baturong Limestone member of the chert- spilite formations, North Borneo. Geol. Magazine 99, 4, p. 289-303.
(Madai-Baturong limestone of Semporna Peninsula, SE Sabah, forms important marker horizon in 'oceanic' Chert-Spilite Fm. Steeply NE-dipping, up to 2000' thick at Mt Madai. At Mt Madurong with oolite beds. In lower part with Lower? Cretaceous shallow marine algae (Lithocodium, Cayeuxia, Hensonella) and Dictyoconus foram. Upper part and breccias with U Cretaceous deep marine planktonic foraminifera (Campanian Globotruncana, Heterohelix, Praeglobotruncana). Chert-Spilite Fm uplifted against Upper Tertiary sediments along thrust fault. (Interpreted as seamount deposit on oceanic crust high by Lee (2003))

Adams, C.G. & H.J.C. Kirk (1963)- The Madai-Baturong Limestone member of the chert- spilite formations, North Borneo. In: F.H. Fitch (ed.) Proc. British Borneo Geological Conference 1961, Kuching, Geol. Survey Dept., British Territories in Borneo, Bull. 4, Kuching, p. 79-86.
(Same paper as Adams & Kirk 1962)

Adams, C.G. & G.E. Wilford (1972)- On the age and origin of the Keramit and Selidong Limestones, Sarawak, East Malaysia. Geol. Survey Malaysia, Geological Papers 1, p. 28-42.
(Keramit and Selidong limestones deposited in moderately deep water; Eocene and Oligocene shales with pelagic foraminifera interbedded with calcarenites with Late Oligocene (Lower Te) larger foraminifera)

Adams, E.W., R.E. Besems & S.J. Gough (2012)- ñPre-MMUò carbonates and the influence of age and tectonic regimes on their growth styles, Sarawak, Malaysia. In: Petroleum Geoscience Conf. Exhibition (PGCE 2012), Kuala Lumpur, Warta Geologi 38, 2, p. 120-121.
(online at: https://gsmpubl.files.wordpress.com/2014/09/warta38_21.pdf)

(Extended Abstract. 'Traditional' offshore Sarawak carbonate exploration is in M-Late Miocene Luconia Province carbonates, above 'M Miocene unconformity (MMU)', when many of the Luconia Province carbonates initiated during major M Miocene flooding. Carbonates also in 'pre-MMU' section. U Eocene-Lw Oligocene carbonates onshore Sarawak, developed speculatively as isolated thrust-top platforms, in front of Rajang accretionary wedge as result of Luconia Block docking against Borneo. Late Oligocene relatively stable, regionally extensive shelf system. Shift from foram-and-algal to coral-dominated carbonate deposition at Oligocene-Miocene boundary)

Adams, E.W., P.F.M. Janssen, S. Ghani, S.J. Gough & P. Winefield (2013)- The Lower Miocene Great Barrier Reef of Sarawak, Malaysia: the exploration potential of Cycle II and III carbonates. In: Petroleum Geoscience Conf. Exhib. (PGCE 2013), Kuala Lumpur, O25, 3p. *(Extended Abstract)*
(E Miocene (~20 Ma) widespread passive shelf-margin carbonate deposition in distal part of NW-SE trending paleo-Sarawak shelf, from northern C Luconia in NW to onshore Sarawak in SE. High-relief carbonate platform margin developed, and in some locations continued into M-Late Miocene Luconia Province carbonates. Vast parts of Lower Miocene Cycle II and III carbonates have poor primary reservoir properties)

Algar, S. (2012)- Big oil from ñgas-proneò source rocks and leaking traps: Northwest Borneo. AAPG Int. Conf. Exhib., Singapore 2012, Search and Discovery Art. 10465, p. 1-40. *(Abstract and Presentation)*
(online at: www.searchanddiscovery.com/documents/2012/10465algar/ndx_algar.pdf)
(Murphy 2002 Kikeh Field oil discovery in offshore Sabah deepwater (>400 MMBO) in deepwater sands in thrust structure. Oil source material M Miocene terrestrial plant material, present mainly in sandstones. Most oil fields on Sabah shelf have abundant crestal faulting; presence of oil fields in 'gas province' probably due to gas leakage via faults)

Algar, S., C. Milton, H. Upshall, J. Roestenburg & P. Crevello (2011)- Mass-transport deposits of the deepwater Northwestern Borneo margin- characterization from seismic-reflection, borehole, and core data with implications for hydrocarbon exploration and exploitation. In: R.C. Shipp et al. (eds.) Mass-transport deposits in deepwater settings, Soc. Sedimentary Geology (SEPM) Spec. Publ. 96, p. 351-366.
(In Late Miocene to Recent deep water thrust belt off NW Borneo up to 50% of sediments large-scale remobilized mass-transport deposits. MTD's 10-200m thick, composed mainly of claystone. Intercalated with turbidites, which form sandstone reservoirs of petroleum discoveries. Thickest sands often immediately overlying MTDs. MTD lithofacies continuum from debritic claystones to more simply folded claystones)

Ali, A.M. & E. Padmanabhan (2014)- Quartz surface morphology of Tertiary rocks from North East Sarawak, Malaysia: implications for paleo-depositional environment and reservoir rock quality predictions. Petroleum Expl. Development 41, 6, p. 761-770.
(Study of surface damage of quartz crystals from weathering and diagenesis in Miocene outcrop sandstones from Sarawak. Belait conglomerates with euhedral quartz crystals with mechanical weathering defects, and higher porosity than. Lambir sandstones with more chemical weathering features. Coatings of authigenic clay and iron oxides inhibit or delay cementation, consequently preserving porosity

Ali, M.Y. (1992)- Carbonate cement stratigraphy and timing of hydrocarbon migration: an example from Tigapapan Unit, offshore Sabah. Bull. Geol. Soc. Malaysia 32, p. 185-211.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1992022.pdf)
(Late Miocene Tigapapan Unit one of several hydrocarbon-bearing reservoirs in offshore NW Sabah Basin. Consists of bioclast-rich, clastics, interpreted as progradation storm shoal deposits. Cathodoluminescence, geochemical and isotopic studies indicate 9 stages of carbonate cementation, formed from near surface to 2 km depth. Sr isotope dating of dolomites indicates two events, 10.5 Ma and 8.9 Ma))

Ali, M.Y. (1995)- Carbonate cement stratigraphy and timing of diagenesis in a Miocene mixed carbonate-clastic sequence, offshore Sabah, Malaysia: Constraints from cathodoluminescence, geochemistry, and isotope studies. Sedimentary Geology 99, p. 191-214.
(Similar paper to Ali (1992) on carbonate cementation history in Middle-Late Miocene sandstone reservoir offshore NW Sabah)

Ali, M.Y. (2014)- An integrated analysis of the depositional control, sedimentology and diagenesis of Cenozoic carbonates from the Sarawak Basin, East Malaysia. Ph.D. Thesis Imperial College, University of London, p. 1-467.
(online at: https://spiral.imperial.ac.uk/handle/10044/1/29605)
(Comprehensive analysis of Cenozoic carbonates from Sarawak Basin, both onshore (4 Late Eocene -E Miocene units) and offshore (4 M-L Miocene build-ups in offshore C Luconia). Carbonate growth mainly controlled by paleo-basement structures: some carbonates on flat rift blocks show flat-top morphology; on

tilted sub-blocks often conical shapes. Eustacy probably main controlling mechanism for carbonate growth. Late Eocene Lower Batu Gading Lst massive nummulitic facies with Pellatispira; E Miocene U Batu Gading Lst on disconformity and composed of finely bedded and brecciated limestones. Suai Lst (Te5?) fining-upward parasequences of larger foraminifera dominated by large Eulepidina spp. E Miocene Subis Lst (Te5) rich in corals, foraminifera and algae. Bekenu Lst laminated marls-shale calci-turbidites). Luconia offshore carbonates greater similarity in facies and sequences. Ten stages of calcite cementation/ dolomitisation. Presence of high T minerals indicate late stage corrosive fluids of hydrothermal origin, responsible for porosity- permeability enhancement of reservoirs)

Alias, F.L. (2014)- Organic petrological and organic geochemical of tertiary coals within the west middle block of the Pinangah coal field, Sabah, Malaysia. Masters Thesis, University of Malaya, p. 1-140.
(online at: http://studentsrepo.um.edu.my/4870/)
(Coals of E-M Miocene Tanjong Fm in Pinangah coalfield, Maliau Basin, S Sabah, excellent hydrocarbon-generative potential. Coals humic and dominated by vitrinite, >15% liptinite and low inertinite macerals. Bitumen yields 57,300-140,000 ppm. High hydrogen index up to 300 mg HC/g TOC, consistent with Type II and mixed Type II-III kerogen. Vitrinite reflectance 0.42%-0.66 Ro% (immature- early mature). With Rhizophora, Casuriana, Dactylocdalus and Podocarpus pollen. Deposition on lower delta plain)

Alias, F.L., W.H. Abdullah, M.H. Hakimi, M.H. Azhar & R.L. Kugler (2012)- Organic geochemical characteristics and depositional environment of the Tertiary Tanjong Formation coals in the Pinangah area, onshore Sabah, Malaysia. Int. J. Coal Geology 104, p. 9-21.
(Tertiary Tanjong Fm coals in Pinangah Coalfield, S Sabah, are humic, dominated by vitrinite, with significant liptinite and low inertinite macerals. Total organic carbon 51-78%, with bitumen values 57,300-140,000 ppm, therefore source rock with good hydrocarbon-generative potential. Good liquid hydrocarbons generation potential can also be expected from significant liptinitic content (>15%). Vitrinite reflectance Ro 0.42- 0.66%, indicating immature- early mature stage for hydrocarbon generation)

Alshebani, K.A., W.H. Abdullah & A.H. Abd. Rahman (2003)- Biomarker characterization and thermal maturity evaluation of Ganduman Formation, Sahabat area, Dent Peninsula, E Sabah, Malaysia. Bull. Geol. Soc. Malaysia 46, p. 461-466.
(online at: www.gsm.org.my/products/702001-100617-PDF.pdf)
(Pliocene sediments fluvio-deltaic/ lacustrine Ganduman Fm in Sahabat area of Dent Peninsula, E Sabah, still immature for hydrocarbon generation. Extract of one immature sandstone sample thermally mature, suggesting migrated hydrocarbons)

Anderson, J.A.R. & J. Muller (1975)- Palynological study of a Holocene peat and a Miocene coal deposit from NW Borneo. Review Palaeobotany Palynology 19, p. 291-351.

(Palynology study of Holocene raised peat bog near Marudi (Sarawak) and Miocene coal near Berakas (Brunei) and compared with present-day swamp vegetation along NW Borneo coast. 76 pollen and spore types recognized. Floristic composition of mixed swamp forest stage in both bogs closely comparable. Only one spore type, Stenochlaena areolaris became extinct in Borneo)

Anuar, A., P. Abolins, P. Crevello & W.H. Abdullah (2003)- A geochemical evaluation of the west Crocker Formation- clues to deepwater source rock facies. Warta Geologi 29, 6, p. 267-268. *(Abstract only)*
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm2003006.pdf)
(Geochemistry of outcrop samples from deep water facies of West Crocker Fm around Kota Kinabalu. Pelagic basin floor shales with low organic content (TOC <0.5%) and unlikely source facies. Biomarkers mainly marine signature (even C27, C28, C29 sterane, presence of C30 steranes, absence of higher plant indicators oleanane and bicadinanes and low Tm/ Ts and Pr/Ph ratios). Fine turbiditic shales (levee/overbank deposits or fine tails of turbidity currents with variable TOC (0.11-2.5%); possible source facies. Shales associated with slumps and debris flows with TOC of 0.42- 2.75%. Debris flows can be very carbonaceous, with TOC up to 69%, with biomarkers with strong terrigenous, higher plant signature (marked C29 preference, lack of C30 steranes, high 18a(H) oleanane), suggesting promising source rock facies. Vitrinite reflectance shows variable maturity of West Crocker Fm (Ro 0.65- >2.0%))

Anuar, A. & R.R.F. Kinghorn (1995)- Sterane and iriterpane biomarker characteristics from oils and sediment extracts of the Middle-Upper Miocene sequences, Northern Sabah basin. In: G.H. Teh (ed.) Proc. AAPG-GSM Int. Conf. 1994, SE Asian basins; oil and gas for the 21st century. Bull. Geol. Soc. Malaysia 37, p. 415-436.
(online at: www.gsm.org.my/products/702001-100937-PDF.pdf)
(Biomarker studies on oils and sediments from N Sabah Basin wells show dominantly terrigenous organic matter source for hydrocarbons: high triterpane/sterane ratios, compounds diagnostic of land-derived plant organic matter such as oleanane and resins W, T and R, and predominance of C 29 regular steranes over C27 and C28. Majority of extracted sediments immature (first authors to suggest landplants as main hydrocarbon source in deep marine enviroments around Borneo?; JTvG))

Anuar, A. & A.J. Muhamad (1997)- A comparison of source rock facies and hydrocarbon types of the Middle Miocene sequence, Offshore NW Sabah Basin, Malaysia. In: Proc. Int. Conf. Petroleum Systems of SE Asia and Australasia, Jakarta 1997, p. 773-786.
(Potential source rocks in NW Sabah Basin in three broad paleoenvironments: 1) coastal-lower coastal plain; 2) fluviomarine and 3) continental shelf-deep marine areas. Preservation of organic matter seems related to high productivity, high sediment accumulation rates and resistant nature of Type I11 higher land plant waxes to oxidation and biodegradation. Anoxic depositional conditions not essential for organic matter preservation. Oils discovered in each of these settings similar biomarkers: large oleanane peak, common bicadinanes, and C2q-tetracyclic terpane, but only a small portion of source extracts correlates positively with Sabah oils)

Asis, J., M.N.I. Abdul Rahman, B. Jasin & S. Tahir (2015)- Late Oligocene and Early Miocene planktic foraminifera from the Temburong Formation, Tenom, Sabah. Bull. Geol. Soc. Malaysia 61, p. 43-47.
(online at: www.gsm.org.my/products/702001-101677-PDF.pdf)
(Temburong Fm at Paal River, Tenom district, SW Sabah, fine-grained flysch deposits of distal part of deep-sea fan. Two shale samples with planktonic foraminifera: (1) Globorotalia ciperoensis Zone (P22; Chattian) and (2) Catapsydrax dissimilis-Praeorbulina sicana Zone (N7; late Burdigalian))

Asis, J. & Basir Jasin (2010)- Radiolaria Kapur dalam kompleks ofiolit Teluk Darvel di Sungai Sipit Lahundai, Kunak, Sabah. Borneo Science 27, p. 1-4.
(online at: http://borneoscience.ums.edu.my/wp-content/uploads/2010/09/)
('Cretaceous radiolaria in the Darvel Bay Ophiolite Complex at the Sipit Lahunday River, Kunak, Sabah'. Darvel Bay Ophiolite Complex consists of mafic-ultramafic association, overlain by bedded chert. Bedded chert has abundant radiolarians and is exposed at Sipit Lahundai River, 22 km from Kunak. Three Aptian- Turonian assemblages)

Asis, J. & Basir Jasin (2011)- Some Cretaceous radiolaria from Darvel Bay Ophiolite complex, Kunak, Sabah. Proc. 24th Ann. National Geoscience Conference 2011 (NGC2011), Johor Baru, B13, p. 82. *(Abstract)*
(online at: http://geology.um.edu.my/gsmpublic/NGC2011/NGC2011_Proceedings.pdf)
(Darvel Bay Ophiolite Complex of SE Sabah withperidotite, gabbro, pillow basalt and reddish-brown chert. Cherts along Kunak-Semporna road with 56 species of radiolaria, of 3 assemblages: I: Aptian-Albian, with Sticomitra simplex, Crucella bossoensis, etc.; II: Albian-Cenomanian, with Xitus mclauglini, Pseudoaulophacus sculptus, Dictyomitra gracilis, etc.; III: Turonian, with Pseudotheocampe tina, Crucella cahensis, Dictyomitra multicostata, etc.. Bedded chert with abundant radiolarians indicates high plankton productivity, possibly related to upwelling. Absence of limestone suggests deposition below CCD depth)

Asis, J. & Basir Jasin (2012)- Some Cretaceous radiolaria from Kuamut Melange, Kunak, Sabah. Geol. Soc. Malaysia, Nat. Geoscience Conf., Kuching 2012, Paper A2, p. 9-10.
(E Miocene Kuamut melange with broken Paleogene rock formations and dismembered ophiolite blocks embedded in shale matrix. Chert interbedded with folded siliceous shale and contains Aptian- Turonian radiolaria; slightly longer version below)

Asis, J. & Basir Jasin (2012)- Aptian to Turonian radiolaria from the Darvel Bay Ophiolite Complex, Kunak, Sabah. Bull. Geol. Soc. Malaysia 58, p. 89-96.
(online at: https://gsmpubl.files.wordpress.com/2014/08/bgsm2012013.pdf)
(Darvel Bay Ophiolite Complex (formerly known as Chert-Spilite Fm) of E Sabah composed of ultramafics, basalts, etc., capped by red radiolarian chert. Folded bedded cherts with 56 species of Aptian-Turonian radiolarians in three assemblages. I (Aptian-Albian) with Sticomitra simplex, Crucella bossoensis, Xitus clava, Dictyomitra communis, etc.; II (Albian-Cenomanian)with Xitus mclaughlini, Pseudoaulophacus sculptus, Dictyomitra gracilis, etc.; III (Turonian) with Pseudotheocampe tina, Ultranapora cretacea, Alievium superbum, Crucella cachensis, etc.. Abundance of radiolarians reflects high planktonic productivity. Absence of limestone indicates deposition below Calcite Compensation Depth)

Asis, J. & Basir Jasin (2013)- Aptian to Turonian radiolarians from chert blocks in the Kuamut Melange, Sabah, Malaysia. Sains Malaysiana 42, 5, p. 561-570.
(online at: www.ukm.edu.my/jsm/pdf_files/SM-PDF-42-5-2013/02%20Junaidi.pdf)
(Miocene Kuamut Melange in Kunak district, SE Sabah, probably unconformably overlies Darvel Bay Ophiolite Complex. Consists of broken Paleogene formations and dismembered ophiolite blocks embedded in shale with chert matrix. Fourteen samples from 1-2.5m thick chert-siliceous shale section on pillow basalt, with 45 species of radiolaria. Three assemblages: I (Aptian-Albian), II (Albian-Cenomanian) and III (Turonian). Cherts deposited on floor of marginal ocean basin in Cretaceous and tectonically deformed in melange in M Miocene)

Asis, J. & Basir Jasin (2013)- Miocene larger benthic foraminifera from the Kalumpang Formation, Tawau, Sabah: preliminary interpretation. In: Proc. Nat. Geoscience Conf., Ipoh 2013, Geol. Soc. Malaysia, p. 66-68. *(Extended Abstract only)*
(online at: http://geology.um.edu.my/gsmpublic/NGC2013/…)
(Miocene larger foraminifera from Spit Lst unit of Kalumpang Fm in Teck Guan Quarry, Tawau, SE Sabah, with 14 species of larger foraminifera, incl. Lepidocyclina (Nephrolepidina) spp., Lepidocyclina (Eulepidina), Miogypsina, Cycloclypeus (Katacycloclypeus) annulatus, Flosculinella bontangensis, etc. (most likely age Middle Miocene; Langhian; JTvG). See also Asis and Jasin 2015))

Asis, J. & Basir Jasin (2015)- Miocene larger benthic foraminifera from the Kalumpang Formation in Tawau, Sabah. Sains Malaysiana 44, 10, p. 1397-1405.
(online at: www.ukm.my/jsm/pdf_files/SM-PDF-44-10-2015/04%20Junaidi%20Asis.pdf)
(Samples of Kalumpang Fm/ Sipit Mb reefal limestone in 46m thick section at Teck Guan Quarry, 50km E of Tawau, SE Sabah. Formation faulted and thrusted against Cretaceous Darvel Bay Ophiolite Complex at Darvel Bay area. 17 species of larger foraminifera, in two assemblages: (1) Lepidocyclina (N) parva, L. (Eulepidina) formosa (Te5, Aquitanian-Burdigalian; E Miocene); (2) Lepidocyclina (N) sumatrensis, Lepidocyclina (N) angulosa, Lepidocyclina spp., Miogypsina sp., Katacycloclypeus annulatus, Cycloclypeus spp., Flosculinella bontangensis, etc. (Tf1-2; M Miocene))

Asis, J., S. Tahir, Basir Jasin & B. Musta (2018)- Lower Miocene, larger benthic foraminifera fauna and depositional environment of limestone facies from Batu Luang, Klias Peninsula, Sabah. Bull. Geol. Soc. Malaysia 65, p. 125-130.
(online at: https://gsm.org.my/products/702001-101731-PDF.pdf)
(Limestone unit exposed in Batu Luang with Lepidocyclina (N.) verbeeki assemblage (zone Te5, early Miocene (Aquitanian)). Small reef deposited in shallow marine environment)

Asis, J., S. Tahir, B. Jasin, N. Abdullah & B. Musta (2018)- Larger benthic foraminifera from Early Miocene limestone of the Setap Shale Formation at Batu Luang, Klias Peninsula, Sabah, Malaysia. Int. Research J. Earth Sciences 6, 10, p. 12-19.
(online at: http://www.isca.me/EARTH_SCI/Archive/v6/i10/2.ISCA-IRJES-2018-013.pdf)
(Limestone unit of Setap shale Fm exposed at Batu Luang, Klias Peninsula, Sabah. Limestone with encrusting coral in lower part. Upper part massive, with 11 species of larger foraminifera, incl. Austrotrillina, Lepidocyclina (Eulepidina), Lepidocyclina (Nephrolepidina) spp., Miogypsinoides dehaarti, Spirocyclopeus sp. and Tansinhokella, idicative of Te5, earliest Miocene (older than previous work))

(online at: https://gsm.org.my/products/702001-101739-PDF.pdf)
(Lower Miocene Temburong Fm exposed at SW Klias Peninsula two local biozones, N4 and N5. Deposited in distal deep-sea fan environment in latest Oligocene- earliest Miocene (U Chattian- Aquitanian))

Asis, J., S. Tahir, B. Musta, Basir Jasin, H.F.W. Soehady & D. Gabda (2019)- Paleoclimate of Upper Oligocene-Lower Miocene Temburong Formation, Klias Peninsula, Sabah, base on planktonic foraminifera assemblage. In: 12th Seminar on Science and Technology, J. Physics: Conference Ser. 1358, 012071, p. 1-9.
(online at: https://iopscience.iop.org/article/10.1088/1742-6596/1358/1/012071/pdf)
(Temburong Fm on Klias Peninsula, Sabah composed of flysch-type deposit. Planktonic foraminifera in 9 samples 3 zones, P21-P22, N4 and N5-N6. Cool climate indicators (Catapsydrax, small Globigerina) more common in Late Oligocene sediment, gradually shifted to warm climatic indices (Globigerinoides spp., Globoqudrina altispira) in Lower Miocene section)

Atkinson, C.D., M.J.B.G. Goesten, A. Speksnijder & W. van der Vlugt (1986)- Storm-generated sandstone in the Miocene Miri Formation, Seria Field, Brunei (NW Borneo). In: R.J. Knight & R.J. McClean (eds.) Shelf sands and sandstones, Canadian Soc. Petroleum Geol. Memoir 11, p. 213-240.
(Cores from 20-25m thick reservoir interval in U Miocene Miri Fm, Seria field of Baram Delta Basin composed predominantly of silty-sandy shales interspersed with numerous sandstone beds. Sands two main types: (1) thin (0.1-1.5m), fining-upward units with patchy, sheet-like geometry and lateral extent of 100- 1500m (single storm events); and (2) thicker (1.5- 3m), more extensive (>2 km) amalgamated sands (stacked storm sands of the lower-middle shoreface. Overall shelf regression and shoaling, followed by transgression and deepening)

Barckhausen, U., D. Franke, D. Behain & H. Meyer (2002)- New insight into the crustal structure of the continental margin offshore NW Sabah/Borneo. EGS 27th General Assembly, Nice, EOS Transactions, American Geophys. Union (AGU) 83 (47, Suppl.), p. 1291-1292. *(Abstract only)*
(Continental margin offshore NW Sabah looks like typical accretionary margin, formed during subduction of proto-S China Sea. Presently inactive. Seaward of Sabah Trough extended continental lithosphere, with rotated fault blocks, half grabens and E Oligocene- E Miocene carbonate platform. Continental crust also under Sabah Trough and adjacent continental slope. Dangerous Grounds' extended continental crust can be traced landward of Sabah Trough beneath sediments of upper plate. Magnetic signatures of young volcanic features continue under continental slope. Tectonic scenario for NW Sabah continental margin: Seafloor spreading in S China Sea from ~30 Ma separated Dangerous Grounds area from SE Asia and ceased in late E Miocene when oceanic crust of proto-S China Sea was fully subducted. In E and/or M Miocene, Borneo rotated CCW and was thrusted

onto edge of Dangerous Grounds block. Subducted oceanic crust of proto S China Sea today below E Sabah, not along present NW Sabah Trough)

(Sarawak five Triassic- Cenozoic sedimentary basins. Zircons from Triassic of Sadong-Kuching Basin sourced by Carnian- Norian (mainly ~220-260 Ma) volcanic arc and from Cathaysian rocks with Paleoproterozoic zircons (peak at ~1800-1900 Ma). U Jurassic- E Cretaceous sands of Bau-Pedawan Basin (Pedawan Fm) indicate initiation of subduction below W Sarawak in Late Jurassic, but still with common inherited Cathaysian zircons. Subduction beneath Schwaner Mountains in early Late Cretaceous. After uplift forming Pedawan-

Kayan unconformity two episodes of extension: (1) Kayan Basin in latest Cretaceous- E Paleocene (Kayan Sst zircons mainly M Cretaceous and Triassic), and (2) Ketungau Basin and Penrissen Sst in M-Late Eocene. Zircons indicate nearby volcanic activity throughout E Cenozoic in NW Borneo. Inherited zircon ages indicate alternation between Borneo and Tin Belt source rocks)

Breitfeld, H.T., T. Galin, R. Hall, I. Sevastjanova, M.A. Forster & G.S. Lister (2015)- Provenance and age of Mesozoic to Cenozoic sedimentary successions and tectonic history of West and Central Sarawak. Asia Petrol. Geoscience Conf. Exhib. (APGCE), Kuala Lumpur, 25853, 5p. *(Extended Abstract)*
(Provenance study in Triassic-Cenozoic basins of Kuching (W Sarawak) and Sibu Zones (C Sarawak deep marine Rajang Gp) (separated by 'Lupar Line'). Ar-Ar ages of micas from metamorphic rocks in W Sarawak indicate Late Triassic collisional event. Widespread Triassic volcanic and volcaniclastic rocks associated with subduction; Triassic U-Pb magmatic ages from zircons in Jagoi Granodiorite. Triassic Sadong Fm and deep marine equivalent (Kuching Fm), sourced by Triassic (Carnian-Norian) volcanic arc. Pedawan-Kayan regional unconformity marks end of subduction beneath Sarawak and indicates Late Cretaceous collision. Fluvial Kayan Gp divided into Kayan Sst Fm and Penrissen Sst. Kayan Sst U-Pb detrital zircon ages indicate maximum depositional ages of Undan Mb 71 Ma (Maastrichtian; with Cretaceous and Permo-Triassic zircons), Bungo Mb 62 Ma (Danian; dominated by Cretaceous zircons) and Penrissen Sst 47-51 Ma (Late Ypresian- Lutetian). Ketungau Gp records second episode of terrestrial sedimentation in W Sarawak. Basal Silantek Fm no older than 42 Ma (Lutetian), unconformably on Cretaceous accretionary complex, Tutoop Sst (=Late Eocene- E Oligocene Plateau Sst) and Ketungau Fm. Bako-Mintu Sst in upper part no older than 40 Ma (Bartonian). Kuching and Sibu Zones connected with SW Borneo and Sundaland since Cretaceous)

Breitfeld, H.T., T. Galin, R. Hall, I. Sevastjanova, M. Forster & G. Lister (2015)- Proto-South China Sea and South China Sea early history: a view from Sarawak. AAPG Asia Pacific Workshop Tectonic evolution and sedimentation of South China Sea Region, Kota Kinabalu, Search and Discovery Art. 90236, 4p.
(online at: http://www.searchanddiscovery.com/abstracts/pdf/2015/90236apr/abstracts/ndx_breitfeld.pdf)
(Extended Abstract. New Ar-Ar dating of white micas from supposed basement schists in W Sarawak yielded Triassic ages. Triassic volcanic and volcaniclastic rocks widespread in W Sarawak. Triassic U-Pb magmatic ages from zircons in Jagoi granodiorite, W of Bau. Metamorphism associated with contemporaneous volcanic arc magmatism, recording Triassic subduction and collision)

Breitfeld, H.T. & R. Hall (2018)- The eastern Sundaland margin in the latest Cretaceous to Late Eocene: Sediment provenance and depositional setting of the Kuching and Sibu Zones of Borneo. Gondwana Research 63, p. 34-64.
(Kuching Zone in Borneo several large sedimentary basins of Late Cretaceous- Late Eocene age. W Sarawak Kayan Basin with U Cretaceous- Lower Eocene Kayan and Penrissen Sandstones (Late Cretaceous- Paleocene with abundant Cretaceous, Permian-Triassic and Precambrian zircons; Paleocene- E Eocene mainly Cretaceous zircons from Schwaner granites of SW Borneo). In Kuching Zone Ketungau Basin with unconformably overlying M-U Eocene Ketungau Group, with oldest sediments derived from nearby sources, probably Triassic Sadong and Kuching Fms. Kuching sediments can be correlated with deep marine Rajang Gp. Some magmatism but scarcity of contemporaneous zircons indicates it was very minor)

Breitfeld, H.T., R. Hall, T. Galin, M.A. Forster & M.K. BouDagher-Fadel (2017)- A Triassic to Cretaceous Sundaland- Pacific subduction margin in West Sarawak, Borneo. Tectonophysics 694, p. 35-56.
(online at: http://searg.rhul.ac.uk/pubs/breitfeld_etal_2017%20Triassic-Cretaceous%20Sarawak%20subduction%20margin.pdf)
(Metamorphic rocks in W Sarawak previously assumed to be pre-Carboniferous basement but new Ar/Ar ages from quartz-mica schists show Late Triassic metamorphism (~216-220 Ma; Norian). Metamorphics associated with Triassic acid and basic igneous rocks. Late Triassic Sadong Fm with youngest zircon ages of ~205, 212 Ma and inherited age peaks of 240-270 Ma and 1.8 Ga. Zircon ages from Jagoi Granodiorite ~208 Ma with inherited ages of 240 Ma, reflecting M-L Triassic subduction in W Sarawak (most likely W-directed Paleo-Pacific subduction). W Sarawak and NW Kalimantan underlain by continental crust that was already part of Sundaland in Triassic. Detrital zircon ages in Cretaceous volcanoclastic Pedawan Fm with major peaks 110-120, 150-160, 220-240, 250-260 Ma, 1.8-1.9 Ga), similar to ages of Schwaner granites of SW Kalimantan plus

additional sources; interpreted as Cretaceous forearc basin with material eroded from magmatic arc that extended from Vietnam to W Borneo. Youngest ages from zircons in tuff layer from uppermost Pedawan Fm indicate end of volcanic activity/ subduction at ~86-88 Ma. Cretaceous metamorphism of Serabang, Sejingkat, Sebangan Fms and Lubok Antu- Kapuas (and Boyan?) melange associated with Cretaceous subduction zone. Results of study cast doubt on existence of separate 'Semitau block')

Breitfeld, H.T., R. Hall, T. Galin, M.A. Forster & M.K. BouDagher-Fadel (2018)- Unravelling the stratigraphy and sedimentation history of the uppermost Cretaceous to Eocene sediments of the Kuching Zone in West Sarawak (Malaysia), Borneo. J. Asian Earth Sci. 160, p. 200-223
(online at: http://searg.rhul.ac.uk/pubs/breitfeld_etal_2018%20Kuching%20provenance.pdf)
(Kuching Zone in W Sarawak two sedimentary basins (Kayan, Ketungau) that extend into Kalimantan. Uppermost Cretaceous (Maastrichtian)- Lower Eocene Kayan Gp above Pedawan Unconformity, marking end of Paleo-Pacific subduction-related magmatism (above Cretaceous Pedawan Fm forearc sediments). Kayan and Penrissen Sst mainly fluvial- alluvial fan deposits. In late E or early M Eocene, sedimentation in basin ceased and Ketungau Basin developed to E. Change marked by Kayan Unconformity. Sedimentation resumed in M Eocene (Lutetian) with marginal marine Ngili Sst and fluvial Silantek Fm. Top of Ketungau Gp fluvial-dominated Tutoop Sst. Paleocurrent measurements show dominant southern source, suggesting uplift of S Borneo in region of Schwaner Mountains from latest Cretaceous onwards. Ketungau Gp also with reworked Kayan Gp. Kuching Supergroup predominantly horizontal or low dips, with steep dips restricted to faults)

Breitfeld, H.T., J. Hennig, M.K. BouDagher-Fadel & R. Hall (2017)- The Rajang unconformity: major provenance change between the Eocene and Oligo-Miocene sequences in NW Borneo. American Geophys. Union (AGU) Fall Meeting, New Orleans, EP21A-1829, 1p. *(Poster Presentation)*
(online at: https://agu.confex.com/agu/fm17/meetingapp.cgi/Paper/223716)
(Detrital zircon age distributions suggest major change in provenance at unconformity between E-M Eocene deepwater Belaga- Bawang Fms and fluvio-deltaic Oligo-Miocene Tatau-Nyalau Fms. Unconformity previously interpreted as Late Eocene orogeny, but no evidence for subduction or collision event at this time in Sarawak; possibly marks late M Eocene plate reorganisation. Borneo main source of Cretaceous (~120-150 Ma peak?) zircons (Schwaner Mts, W Sarawak). Dominant Triassic (~220-240 Ma peak?) zircon age population in Nyalau Fm indicates either provenance from Malay Peninsula tin belt or Indochina (SE Vietnam). (or unidentified Triassic granites on Borneo? Persistent ~1800 Ma age peak; HvG))

Breitfeld, H.T., C.G. Macpherson, R. Hall, M. Thirlwall, C.J. Ottley & J. Hennig-Breitfeld (2019)- Adakites without a slab: remelting of hydrous basalt in the crust and shallow mantle of Borneo to produce the Miocene Sintang Suite and Bau Suite magmatism of West Sarawak. Lithos 344-345, p. 100-121.
(Neogene magmatic rocks of W Sarawak E Miocene West Sarawak Sintang Suite (~19- 21 Ma) and M Miocene Bau Suite (~12-14 Ma). Magmatism in multiple short-lived pulses from ~24 Ma and coeval with magmatic activity in NW and E Kalimantan. Bau Suite mainly adakitic, W Sarawak Sintang Suite mainly non-adakitic. No active subduction zone or slab associated with adakitic magmatism. Mafic mantle-derived magma with felsic magma from remelting of hydrous, mafic rock emplaced into Borneo lithosphere previously, suggesting intraplate, mantle-derived magmatism responsible for remelting older hydrated basaltic rocks in crust)

Chung, W.K. & D. Ghosh (2017)- Growth timing of Southern Field High carbonates, Central Luconia Province. In: M. Awang et al. (eds.) Proc. Int. Conf. Integrated Petroleum Engineering and Geosciences (ICIPEG2016), Kuala Lumpur 2016, Springer Verlag, p. 491-497.
(Growth timing of studied Miocene carbonate platform at C Luconia Province ~ 4 Myrs, governed by third-order sea-level fluctuations and syndepositional tectonics. First karstification during Burdigalian sea-level drop, over complex horst- graben setting, configured by seafloor expansion of S China Sea, before carbonate initiation. Second major subaerial exposure/ karstification in Langhian. Third subaerial exposure minor karstification. Final drowning in Serravallian without subaerial exposure)

Chung, W.K., D. Menier, S.N.F. Jamaludin & D. Ghosh (2016)- Geomorphology and karstification of the Southern Field High carbonates in Central Luconia Province. Proc. Offshore Technology Conference Asia, Kuala Lumpur 2016, OTC-26650-MS, 16p.
(Miocene carbonate platform development of Southern Field High of C Luconia Province. Initial patchy growth during Burdigalian, followed by build-out and backstepping. Four 3rd order Burdigalian-Serravallian eustatic cycles prior to platform drowning and rapid proto-Borneo clastic influx. With extensive karst development by sub-aerial exposure and re-submergence of carbonate platforms. Karstification mainly along fractures and faults. Final drowning correlated to surge of sea level rise in Serravallian)

Church, J. & Bong Poh Yuk (2012)- The Seria Field, Brunei...80 years on...near field exploration going strong! Int. Petrol. Techn. Conf. (IPTC), Bangkok 2012, 3, IPTC 15199, p. 2849-2852.
(Seria oil field in onshore discovered in 1929 and produced >1.1 billion BO. Production peaked 120,000 BOD in 1956. Field still has undeveloped hydrocarbon resources on N flank under shallow surf zone, to be targeted by onshore 'fish-hook wells')

Clark, J. (2017)- Neogene tectonics of Northern Borneo: a simple model to explain complex structures within Miocene-Recent deltaic-deepwater sediments both onshore and offshore. In: SEAPEX Exploration Conference 2017, Singapore, Session 7, 26p. *(Extended Abstract + Presentation)*
(All Neogene deformation across N Borneo is result of uplift and erosion of detached, gravity-driven collapse system and shale diapyrism, not product of multi-phase basement tectonics. Deep Regional Unconformity may not be unconformity, rather diachronous mechanical boundary of different responses of overpressured shale and more competent sandy sediments to gravity-driven collapse)

Clark, J., P. Owen, S. OôBrien & B. Dawe (2015)- Central Luconia carbonates- ôShooting fish in a barrelô: insights into success and failure mechanisms in a mature gas province. Proc. 2015 SE Asia Petroleum Expl. Soc. (SEAPEX) Conference, Singapore, 5.3, p. 1-4. *(Extended Abstract)*
(>110 wells drilled in C Luconia area since 1968, offshore Sarawak, discovering 50 TCF gas-in-place, mainly in Late Miocene carbonate buildups. Lack of charge (migration focus) principal cause of failure in carbonate structures, with presence of seal (presence or absence of 'thief beds') over buildups a secondary factor)

Clark, J., P. Owen, S. OôBrien, B. Dawe (2017)- Central Luconia carbonate exploration- an update after three more SK408 wildcats, has the story changed? In: SEAPEX Exploration Conference 2017, Singapore, Session 7, 3p. *(Extended Abstract + Presentation)*
(In C Luconia province off Sarawak 60 TCF gas in-place discovered, majority in Late Miocene carbonate buildups play. Many carbonate buildups underfilled, probably due to 'thief beds'. Since 2015 paper two more discoveries made in SK408 PSC, including accumulation with gas column height >900m)

Clennell, B. (1991)- The origin and tectonic significance of melanges in Eastern Sabah, Malaysia. J. Southeast Asian Earth Sci. 6, 3-4, p. 407-429.
(E Sabah melanges composed mainly of deep water clastics, deposited in C Sabah Basin, mixed with exotic ophiolitic material. Melanges not metamorphosed; vitrinite reflectance data suggest maximum temperature of <120°C in matrix. Ophiolitic blocks commonly have tectonic shearing fabrics associated with low temperature metamorphism and interpreted as inherited from shear in ocean floor environment (e.g. fracture zones) or associated with ophiolite obduction. All melanges of E Sabah formed in series of related events in late E Miocene and earliest M Miocene time. These events, which triggered sedimentary, diapiric and tectonic melange-forming processes, are related to coeval onset of extension and sea floor spreading in SE Sulu Sea)

Clennell, M.B. (1992)- The melanges of Sabah, Malaysia. Ph.D. Thesis, University of London, p. 1-404. *(Unpublished)*

Clennell, M.B. (1996)- Far-field and gravity tectonics in Miocene basins of Sabah, Malaysia. In: R. Hall & D.J. Blundell (eds.) Tectonic evolution of SE Asia, Geol. Soc. London, Spec. Publ. 106, p. 307-320.
(Oceanic spreading ceased in S China Sea at ~17 Ma, after start of collisions of Asian mainland continental blocks and NW Borneo and Palawan, causing uplift, erosion and 'Deep Regional Unconformity' in NW Sabah. During compression at S margin of S China Sea, Sulu Sea underwent extension, with rifting in NW and oceanic spreading in SE. E Sabah changed from deep marine clastic depositional environment in Oligocene- E Miocene, to shallow marine and terrestrial sedimentation in M-L Miocene, with melange formation at time of the Deep Regional Unconformity. Inversion of Miocene in E Sabah limited to edges of basement blocks, which moved by far-field tectonic stresses. Post M Miocene basin evolution Sabah and Sandakan Basin influenced by mud diapirism and sagging of progradational sand-rich sediments into underlying muds and melange units)

Collins, D.S., H.D. Johnson, P.A. Allison & A.R. Damit (2018)- Mixed process, humid-tropical, shoreline-shelf deposition and preservation: Middle Miocene- modern Baram Delta Province, Northwest Borneo. J. Sedimentary Res. 88, 4, p. 399-430.
(Comparision of outcrop analyses of facies and stratigraphic architecture in M Miocene Belait Fm with process-based geomorphological and sedimentological analyses of coastal-deltaic depositional environments in present-day Baram Delta Province)

Collins, D.S., H.D. Johnson, P.A. Allison, P. Guilpain & A.R. Damit (2017)- Coupled ǿstorm-floodô depositional model: application to the Miocene- modern Baram Delta Province, north-west Borneo. Sedimentology 64, 5, p. 1203-1235.
(manuscript online at: https://core.ac.uk/download/pdf/77017250.pdf)

(Miocene -Recent Baram Delta Province 9-12 km of coastal-deltaic to shelf sediments over past 15 Myr. Facies analysis of outcrops suggests 'storm-flood' depositional model, with two distinct periods: (1) fair-weather periods dominated by longshore sediment reworking and coastal sand accumulation; and (2) monsoon-driven storm periods characterised by increased wave energy and offshore-directed downwelling storm flow that occur simultaneously with peak fluvial discharge caused by 'storm-floods')

Collins, J.S.H., C. Lee & J. Noad (2003)- Miocene and Pleistocene crabs (Crustacea, Decapoda) from Sabah and Sarawak. J. Systematic Palaeontology 1, 3, p. 187-226.
(Three new genera and 20 new species of Miocene and Pleistocene fossil crabs described from area SW of Miri, Sarawak and Sandakan Peninsula of E Sabah. See also Morris & Collins 1991)

Cottam, M., R. Hall, C. Sperber & R. Armstrong (2010)- Pulsed emplacement of the Mount Kinabalu granite, northern Borneo. J. Geol. Soc., London, 167, 1, p. 49-60.
(Sabah Mt. Kinabalu pluton at least four discrete pulses of intrusion. Concentric growth zones in zircons indicate crystallization between 7.85- 7.22 Ma, and show pluton was emplaced in <800 kyrs. Oldest ages coincide with highest elevations. Inherited zircon ages indicate Upper Unit derived from S China margin attenuated continental crust, subducted beneath Sabah. Middle Unit sourced from melting of crystalline basement in Sabah)

Cottam, M., R. Hall, C. Sperber, B.P. Kohn, M.A. Forster & G.E. Batt (2013)- Neogene rock uplift and erosion in Northern Borneo: evidence from the Kinabalu granite, Mount Kinabalu. J. Geol. Soc., London, 170, 5, p. 805-816.
(*Kinabalu granite emplaced between ~7.2-7.8 Ma. Late Miocene- E Pliocene rapid exhumation and uplift of granite demonstrated by radiometric ages of (1) biotite (40Ar/39Ar; 7.3-7.6 Ma), (2) zircon fission-track (6.6-5.8 Ma) and (3) apatite (~5.5 Ma). Emplacement and exhumation of Kinabalu granite not related to Sabah orogeny (terminated in E Miocene), but caused by extension related to subduction rollback of Sulu Arc)*

Cotton, L.J., P.N. Pearson & W. Renema (2014)- Stable isotope stratigraphy and larger benthic foraminiferal extinctions in the Melinau Limestone, Sarawak. J. Asian Earth Sci. 79A, p. 65-71.
(Major extinction of larger foraminifera close to Eocene-Oligocene boundary in Melinau Limestone already recognized by G. Adams. Isotope analyses (δ13C and δ18O) of rock samples studied by Adams show end-Eocene LBF extinction event in Melinau Limestone below isotope excursion)

Couzens-Schultz, B.A. & K. Azbel (2014)- Predicting pore pressure in active fold-thrust systems: an empirical model for the deepwater Sabah foldbelt. J. Structural Geol. 69B, p. 465-480.
(Deepwater Sabah well data used for empirical model for predicting pore pressure in active fold-thrust belt)

Cox, L.R. (1948)- Neogene Mollusca from the Dent Peninsula, British North Borneo. Schweizer. Palaeontol. Abhandlungen 66, 2, p. 3-70.
(Molluscs from Late Miocene- Pliocene sandy marls and clays near E tip of Dent Peninsula. Discusses proportion of living species, geologic ranges and index species).

Crevello, P.D. (2001)- The great Crocker submarine fan: a world-class foredeep turbidite system. Proc. 28th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 378-407.
(Major Late Eocene-Early Miocene submarine fan complex off N Borneo, covering >25,000 km2)

Crevello, P.D., H.D. Johnson, F. Tongkul & M.R. Wells (2008)- Mixed braided and leveed-channel turbidites, West Crocker Fan system, Northwest Borneo. In: T.H. Nielsen et al. (eds.) Atlas of deep-water outcrops, American Assoc. Petrol. Geol. (AAPG), Studies in Geology 56, p. 50-72.
(Chapters 13-19 on examples of turbidite facies of outcrops in NW Borneo)

Crevello, P., C. Morley, J. Lambiase & M. Simmons (1997)- The interaction of tectonics and depositional systems on the stratigraphy of the active Tertiary shelf margin of Brunei Darussalam. In: J.V.C. Howes & R.A.

Noble (eds.) Proc. Int. Conf. Petroleum Systems of SE Asia and Australasia., Jakarta, Indon. Petroleum Assoc. (IPA), p. 767-772.
(M Miocene-Recent stratigraphy of Brunei Darussalam series of seaward younging basins. More than 15 km of deltaic marine sandstone and shale deposited in migrating depocenters. Sediments derived from nearby uplifted Crocker-Rajang accretionary range. Region dominated by at least three delta complexes)

Cullen, A.B. (2010)- The Klias Peninsula and Padas River: NW Borneo, an example of drainage capture in an active tropical foreland basin. AAPG Conv. 2010, New Orleans, Search and Discovery Art. 50294, 7p.

Cullen, A.B. (2010)- Transverse segmentation of the Baram-Balabac Basin, NW Borneo: refining the model. Petroleum Geoscience 16, p. 3-29.
(W Baram Line separates two petroleum systems: (1) SW: Oligocene sst- Lower Miocene carbonate reservoirs of gas-prone Luconia system; (2) NE: oil-rich Baram-Balabac Basin in M Miocene- E Pliocene sst deposited in foreland basin. Baram-Balabac Basin four structural domains, with NW-SE trending boundaries similar to strike of W Baram Line. Domain boundaries probably deep structures in underlying rifted continental crust. Basin post-dates Sarawak Orogeny Eocene-E Oligocene collision of Dangerous Grounds-Reed Bank with Sabah and Palawan. Minimal Oligo-Miocene subduction of oceanic crust under NW Borneo. Sabah Orogeny and younger inversion events related to underthrusting of Dangerous Grounds driven by S China Sea opening and NW-directed subduction beneath SE Sabah)

Cullen, A. (2011)- Influence of hinterland bedrock lithologies on aspect of Borneo's deepwater fold and thrust belt. Berita Sedimentologi 21, FOSI- IAGI, p. 9-14.
(Online at: www.iagi.or.id/fosi/files/2011/06/FOSI_BeritaSedimentologi_BS-21_June2011_Final.pdf)
(Catchment areas of Borneo's major river systems different bedrock lithologies, affecting provenance type and potential reservoir quality. U Cretaceous-Paleogene deepwater Rajang-Embaluh Gp clastics main source of reworked quartzose sands shed into Kutei, Tarakan and Baram Basins. Much of Baram basin mud-dominated source, influencing development of raised peat mires, and structural style of deep water fold- thrust belt)

Cullen, A. (2012)- Nature and significance of the West Baram Line, NW Borneo. AAPG Int. Conv. Exhib., Singapore 2012, Search and Discovery Art. 30252, 12p.
(online at: www.searchanddiscovery.com/documents/2012/30252cullen/ndx_cullen.pdf)
(Boundary between Luconia-Balingian carbonate province in SW and Baram clastics-dominated basin in NE placed along W Baram and Tinjar Lines. This is is not large-scale E Miocene transform fault, but ancient crustal discontinuity that was persistently re-activated in Cenozoic)

Cullen, A. (2014)- Nature and significance of the West Baram and Tinjar Lines, NW Borneo. Marine Petroleum Geol. 51, p. 197-209.
(West Baram- Tinjar Line not transform boundary between Luconia and Dangerous Grounds, but boundary between domains of continental crust that underwent differential extension in Eocene. Baram Basin underlain by hyperextended continental crust on NE side of Baram Line, with Luconia in SW more rigid block)

Cullen, A., C. Macpherson, N.I. Taib, A. Burton-Johnson, D. Geist, T. Spell & R.M. Banda (2013)- Age and petrology of the Usun Apau and Linau Balui volcanics: windows to central Borneoȏs interior. J. Asian Earth Sci. 76, p. 372-388.
(Usun Apau plateau in Sarawak along Tinjar Line, which defines onshore part of suture between Luconia and Dangerous Grounds blocks. Plateau made of dacite and andesite erupted between 3.9- 4.1 Ma, and minor basaltic dikes and flows (~2.1 Ma) represening younger episode of volcanism, similar in age and character to Linau Balui basalts 100 km SE of plateau. Volcanics too young to be linked to subduction beneath Borneo. Isotope ratios indicate assimilation of old, possibly Precambrian, continental crust, and similar to Pliocene volcanics of South China Sea and Sulu Arc)

Cullen, A., M.S. Zechmeister, R.D. Elmore & S.J. Pannalal (2012)- Paleomagnetism of the Crocker Formation, northwest Borneo: implications for late Cenozoic tectonics. Geosphere 8, 5, p. 1146-1169.

(Paleomagnetic study of Eocene- E Miocene sandstones from NW Sabah Crocker Fm. Sandstones pervasively remagnetized. Mean ChRM directions for 7 locations between Kota Kinabalu and Keningau indicate minor CW rotation, two locations near Tenom record CCW rotation. Remagnetization between 35-15 Ma. Probably early episode of regional CCW rotation before 35 Ma, overprinted by CW rotation of crustal blocks during opening of S China Sea (32-23 Ma), and also locally by CCW rotation after 10 Ma)

Cummings, R.H. (1955)- A preliminary account of foraminifera from the Carbo-Permian, West Sarawak. Annual Report Geological Survey Dept., British Territories in Borneo, 1955, p. 79.

Cummings, R.H. (1962)- Limestones of the Terbat Formation, West Sarawak. Annual Report Geological Survey Dept., British Territories in Borneo, 1961, p. 36-48.
(Terbat Limestone Fm in W Sarawak with fusulinid foraminifera assigned to Early Permian (Wolfcampian; = (Asselian- Artinskian?) Pseudoschwagerina zone (Pseudoschwagerina heritschi, P. uber, Paraschwagerina, Schwagerina). Associated small foraminifera suggest local correlation with Sumatra and Malaya (incl. Nummolostegina cf. velebitana, Pseudotextularia sumatrensis, Cribrogenerina sumatrana, Climacammina elegans (= similar to Bigenerina/ Cribrostomum elegans from Permian of Sumatra) (For Davydov et al. 2013 these forms signify broad latest Carboniferous- E Permian age. See also Fontaine 1990; JTvG))

Curiale, J., J. Morelos & W. Mueller (2000)- Molecular and isotopic compositional characteristics of Brunei oils; implications for source rock depositional setting. AAPG Ann. Mtg., Abstracts, p. A28. *(Abstract only)*
(Brunei oils highly paraffinic, enriched in pristane relative to phytane, rich in oleanane and bicadinanes, enriched in C29 steranes relative to C27 and C28, and relatively depleted in extended homohopanes, consistent with presence of angiospermous organic matter and probably implying origin from coals or coaly shales)

Curiale, J., J. Morelos, J. Lambiase & W. Mueller (2000)- Brunei Darussalam- characteristics of selected petroleums and source rocks. Organic Geochem. 31, p. 1475-1493.
(Three Tertiary deltaic complexes deposited up to 10 km of sediments. Strong correlations between certain molecular maturity indicators and present-day temperature of reservoirs. Liquid hydrocarbon source potential in tidal and coastal embayment facies, and greatest in Miocene coals)

Darman, H. & A.R. Damit (2003)- Structural control on sediment distribution in offshore Brunei Darussalam, South China Sea. Proc. 29th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, p. 347-353.
(Brunei offshore Neogene clastics compartmentalized by faults controlled by gravitational gliding and tectonics. Two types of fault systems, NW dipping down-to-basin faults and SE dipping, counter-regional faults)

Darman, H., A. Sabli, A. Ang, S. Daud, H. Dejong, Bong Poh Yuk, A.R. Damit, M. Tajuddin (2007)- The depositional model of the Upper Miocene section of the eastern offshore Area of Brunei Darussalam. Proc. 31st Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA07-G-086, 7p.
(Study of Upper Miocene sandstone reservoir distribution on area of Champion, Iron Duke Field and Bugan fields, ~30 km NW of Bandar Seri Begawan. Sediment distribution controlled by structural events)

De Coo, J.C.M. & J.W.E. Lau (1977)- Recognition of reef facies in the Bau limestone (Upper Jurassic- Lower Cretaceous), Sarawak. Geol. Survey Malaysia, Geological Papers 2, p. 72-78.
(Brief survey of facies in Late Jurassic- Early Cretaceous Bau Limestone S of Kuching, W Sarawak. Deposited in reefal setting, mostly oncolite- algal and pelletal back-reef facies. Reef facies rudist-gastropod boundstone and coralgal boundstone. No facies maps)

Dedeche, A.R., B. Pierson & A. Hunter (2013)- Outcrop analogs to the offshore Sarawak Miocene fields, how effective can they be? The Subis limestone as an example. Proc. Petroleum Geoscience Conf. Exhib. (PGCE), Kuala Lumpur 2013, 30p. *(Presentation only)*
(online at: https://seacarledu.files.wordpress.com/2016/06/2015_12_10_dedeche_niah_outcrop-analogs.pdf)
(Gunung Subis large flat-topped limestone hill in Sarawak still represents shape of original E Miocene backstepping isolated carbonate platform. Similar to S China Sea/ Luconia carbonate buildups in terms of growth history, but different diagenetic history)

Dedeche, A.R., B. Pierson & A. Hunter (2013)- Growth history and facies evolution of the Subis Limestone- a carbonate platform exposed onshore Borneo Island, Malaysia. Proc. 75th EAGE Conf. Exhib., Carbonate depositional environments and diagenesis, London, 1, TuP15 08, p. 55-57.
(presentation online at: https://seacarledu.files.wordpress.com/2016/06/2015_12_10_dedeche_niah_outcrop-analogs.pdf)
(Subis Limestone onshore Sarawak (with Niah cave) 2 main sequences: (1) U Oligocene lower sequence, deep marine; (2) Lower Miocene upper sequence; reefal, and forming spectacular limestone hill that reflects original carbonate platform. Good analogue to Sarawak offshore carbonate platforms)

Haak, R. (1955)- A study of the Miocene Gunong Subis Limestone complex. Shell Group Report, 25948, p. 1-30. *(Unpublished)*
(Haile 1962: Subis Lst member of Setap Shale is isolated reefal carbonate platform dated as latest Oligocene (Te1-4 in Subis 2 well; with Heterostegina borneensis, Miogypsinoides ubaghsi), continuing into basal Miocene

(Te5; with Miogypsinoides dehaartii, Sproclypeus spp., Austrotrillina howchini, etc.) at Bukit Subis outcrop. Thickness 5900' in Subis 2 well, more commonly ~3000' thick. Locally common corals)

Hadley, D.F., E. Arochukwu, K. Nishi, M. Sarginson, H. Salleh & M. Omar (2006)- Depositional modelling of Champion Field, Brunei: assessing the impact of reservoir architecture on secondary recovery. In: Proc. SPE Asia Pacific Oil Gas Conf., Adelaide 2006, 30p.
(Champion field multi-billion bbl STOIIP oilfield off Brunei, producing since 1972 from >250 wells. Production to date is <20% of original oil in place. Two main reservoir types: (1) stacked shoreface parasequences (majority of reservoirs); (2) tide-dominated sediments channel fill or bar complexes)

Hageman, H. (1987)- Palaeobathymetrical changes in NW Sarawak during Oligocene to Pliocene. Bull. Geol. Soc. Malaysia 21, p. 91-102.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1987005.pdf)
(Comparison of NW Sarawak Oligocene-Pliocene paleobathymetric history with global curve suggest Middle Miocene- Pliocene changes largely controlled by eustacy, but Late Oligocene- E Miocene global changes masked by tectonic movements)

Haile, N.S. (1952)- The coal deposits and geology of part of the Klingkang Range, West Sarawak, with a detailed account of the Silantek and Abok seams. Geol. Survey Dept., British Territories in Borneo, 30p.
(Tertiary (probably Eocene) coal-bearing beds outcrop along N scarp of Klingkang Range over ~18 miles. Several seams, interbedded with Tertiary estuarine deposits. Coal high-grade bituminous in rank, may be due to metamorphism caused by emplacement of nearby igneous intrusions)

Haile, N.S. (1954)- The geology and mineral resources of the Strap and Sadong Valleys, West Sarawak, including the Klingkang Range Coal. British Territories in Borneo Region Geol. Survey, Memoir 1, p. 1-150.
(W Sarawak Strap-Sadong valley area with intensely folded Carboniferous-Permian (grey Terbat Lst with fusulinids, white chert and shale) and U Triassic (clastics with Monotis and Halobia, becoming more sandy to S and E). Unconformably overlain by thick E Tertiary non-marine Silantek Fm shale-dominated series with thin coals and brackish water molluscs and >1000m of Plateau Sandstone. Igneous rocks: pre-Triassic granite, Triassic lavas and tuffs and Tertiary shallow igneous stocks and sills. Workable quantities of probably Eocene-age coal, small amounts of gold, diamonds, bauxite, etc.)

Haile, N.S. (1956)- Limestone reserves in the Batu Gading area on the Baram River. British Borneo Geol. Survey Ann. Report, Kuching, p. 30-38.

Haile, N.S. (1957)- The geology and mineral resources of the Lupar and Saribas Valleys, West Sarawak. Malaysia Geol. Survey Borneo Region, Memoir 5, p. 1-123 + 125,000 scale map.
(Lupar-Saribas valley region complex geology, between two different tectono-stratigraphic regions: to W U Paleozoic- Mesozoic, to NE U Cretaceous- Tertiary sediments. With isoclinally folded, steeply (dominantly S-?) dipping deep marine 'flysch-type' U Cretaceous- Lower Eocene Rajang group geosynclinal sediments and volcanics (in slaty facies in N, pelagic 'Danau/Engkilili' calcareous facies with radiolarian chert in S) (= Lubok Antu melange= Paleo-Eocene melange complex with Cretaceous radiolaria, Orbitolina Lst, Assilina, etc.?; see Tan 1979, Haile 1996; JTvG). Unconformably overlain by 'molasse-type' Upper Eocene- Miocene estuarine and continental beds of Plateau series. Late Tertiary intrusive granitic stocks and laccoliths and dolerite sills. Thin-bedded coals in Plateau series and gold-bearing placers exploited on small scale (Marup))

Haile, N.S. (1957)- New evidence of the age of the Plateau Series in West Sarawak. Annual Report Geological Survey Dept., British Territories in Borneo, 1957, p. 77.
(Brief note on presence of Late Eocene (Tb) larger foraminifera Aktinocyclina and Nummulites at base of Kantu Beds (lowest part of Plateau Series), proving Late Eocene or older age of 'Plateau Series transgression' over Pretertiary- Lower Eocene rocks)

Haile, N.S. (1962)- The geology and mineral resources of the Suai-Baram area, North Sarawak. British Borneo Geol. Survey Memoir 13, p. 1-176.

(Suai-Baram area of N Sarawak part of 'North Borneo geosyncline', S of Miri/ Brunei. With >45,000' thick U Cretaceous -Recent sandstones and shales (but U Cretaceous only in one outcrop). Sediments derived from central granitic part of Borneo and later from recycled Cretaceous and Eocene sediments. Pre-Pliocene strata moderately to highly folded. Regional strike N to NE. Major unconformity between Miocene and U Pliocene (E Pliocene folding) (?). Paleocene limestones. Disconformity between U Eocene and Miocene (should be latest Oligocene?; JTvG)(local angular unconformity below base Setap Shale (latest Oligocene; Te1-4) (basal conglomerate with reworked Cretaceous radiolarian chert), missing E Oligocene in Melinau Lst and Batu Gading Lst. Batu Gading Lst 120m of Late Eocene overlain with hiatus by 40m of latest Oligocene (Te1-4) limestone. Subis Lst Mb of Setap shale with Te5/ E Miocene Miogypsinoides dehaarti/ Spiroclypeus (with appendices by Adams & Haak on Batu Gading Lst and Johnson on calcareous algae))

Haile, N.S. (1963)- The Cretaceous- Cenozoic Northwest Borneo geosyncline. In: F.H. Fitch (ed.) Proc. British Borneo Geological Conference 1961, Kuching, Geol. Survey Dept., British Territories in Borneo, Bull. 4, Kuching, p. 1-18.
(NW Borneo Geosyncline with thick Upper Cretaceous- Recent sediments in 500 mile long, 200-250 mile wide belt from Lupar Valley in West Sarawak, all of Brunei, to W part of Sabah. Thirty-two formations distinguished (Liechti et al. 1960), grouped here in 4 lithostratigraphic groups: (1) Rajang Gp (U Cretaceous- Oligocene Te 1-4, C Sarawak- N Kalimantan- W Sabah, foredeep eugeosynclinal grading upward to miogeosynclinal, common flysch, also radiolarian cherts and spilite in Lupar and Danau Fms, intensely folded, up to 50,000' thick?); (2) Baram Gp (U Eocene- U Miocene, miogeosynclinal, unconformable over Rajang Gp, 28,000' thick); (3) Plateau Gp (U Eocene- ?Miocene 'molasse-type' sediments in 'backdeep' after Late Eocene folding; Melawi- Ketungau basins; up to 30,000' thick?) (should be foredeep?) and (4) Brunei Gp (U Miocene- Pliocene in coastal areas of Brunei- NE Sarawak; late geosynclinal isolated basins, ~30,000' thick?))

Haile, N.S. (1968)- The Northwest Borneo geosyncline in its geotectonic setting. Bull. Geol. Soc. Malaysia 1, p. 59. *(Abstract only)*
(Summary of Haile (1969) paper. One of last tectonics papers of SE Asia to use geosynclinal theory)

Haile, N.S. (1969)- Geosynclinal theory and the organizational pattern of the North-West Borneo geosyncline. Quart. J. Geol. Soc., London, 124, 2, p. 171-188.
(NW Borneo geosyncline of Sarawak, Brunei and W Sabah, ~800 km in NE-SW direction. Thick Late Cretaceous- late Cenozoic sequence, classified into 4 groups: (1) Rajang Gp (Late Cretaceous- E Miocene): thick, folded flysch with chert-ophiolite at base; (2) Baram Gp (Late Eocene- Late Miocene): mainly argillaceous, with sandstones and limestones; (3) Plateau Gp (Late Cretaceous to? Miocene): thick molasse-type continental deposits in S; (4) Brunei Gp (Oligocene to Recent): estuarine and marine deposits with molasse affinities in N. Migration of flysch deposition, orogeny, and molasse deposition, from S to N)

Haile N.S. (1992)- Evidence of multiphase deformation in the Rajang-Crocker Range (northern Borneo) from Landsat imagery interpretation: geodynamic implications- Comment (2). Tectonophysics 204, p. 178-180.
(Critical review of Benard et al. 1990 paper)

Haile, N.S. (1996)- Note on the Engkilili Formation and the age of the Lubok Antu Melange, West Sarawak, Malaysia. Warta Geologi (Newsl. Geol. Soc. Malaysia) 22, 2, p. 67-70.
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm1996002.pdf)
(Lupar Valley of W Sarawak is junction of Rajang Group accretionary prism to N and more continental part of W Sarawak to S. Engkilili Fm fossiliferous calcareous shales with Paleocene-E Eocene limestone blocks mapped by Haile as 'lower Eocene calcareous facies', distinct from the main 'cherty' facies, now known as Lubuk Antu melange, to N. Most likely age of melange ~mid-Eocene; Engkilili Beds possibly slightly older)

Haile, N.S., S.K. Lam & R.M. Banda (1994)- Relationship of gabbro and pillow lavas in the Lupar Formation, West Sarawak; implications for interpretation of the Lubok Antu Melange and the Lupar Line. In: G.H. Teh (ed.) GSM Petroleum Geology Seminar VIII, 1991, Bull. Geol. Soc. Malaysia. 36, p. 1-9.
(online at: www.gsm.org.my/products/702001-100981-PDF.pdf)

(Lupar Line regarded by many as major suture, but uncertainties regarding relationship of various belts and rock types. Outcrops for Hydroelectric Project show gabbro in U Cretaceous Lupar Fm bedded flysch is intrusive and pillow lavas interbedded (not older oceanic crust emplaced tectonically as faulted slices). Junctions between Lubok Antu Melange and Lupar Fm, and between Lupar and Layar Fm, may be major sutures, whereas Lupar Valley may only be fault zone in broad melange belt)

Haile, N.S. & N.P.Y. Wong (1965)- The geology and mineral resources of Dent Peninsula, Sabah. British Borneo Geol. Survey Memoir 16, p. 1-199.

Hakimi, M.H. & W.H. Abdullah (2013)- Liquid hydrocarbon generation potential from Tertiary Nyalau Formation coals in the onshore Sarawak, Eastern Malaysia. Int. J. Earth Sciences (Geol. Rundschau) 102, p. 333-348.
(Oligocene- E Miocene coals of Nyalau Fm exposed in N-C onshore Sarawak with TOC of 58-81%, hydrogen index values of 282-510 mg HC/g TOC, Type II and mixed Type II–III kerogens. Vitrinite reflectance 0.47-0.67% Ro, indicating initial oil window maturity. Coals are humic and generally dominated by vitrinite, with significant amounts of liptinite and low amounts of inertinite. Good liquid hydrocarbons generation potential)

Hakimi, M.H., W.H. Abdullah, F.L. Alias, M.H. Azhar & Y.M. Makeen (2013)- Organic petrographic characteristics of Tertiary (Oligocene-Miocene) coals from eastern Malaysia: rank and evidence for petroleum generation. Int. J. Coal Geology 120, p. 71-81.
(Coal samples from Tanjung Fm of Pinangah coalfield (E-M Miocene, Sabah) and Nyalau Fm of Bintulu coal fields (Oligocene- E Miocene, C Sarawak) from N Borneo relatively high hydrogen index values (282 and 516 mg HC/g TOC), indicating coals dominated by Type II to mixed Type II–III kerogens, and considered to generate mainly oil. This is supported byhigh amounts (11-31%) of oil-prone liptinite macerals, incl. suberinite)

Hakimi, M.H., W.H. Abdullah, S.G. Sia & Y.M. Makeen (2013)- Organic geochemical and petrographic characteristics of Tertiary coals in the northwest Sarawak, Malaysia: implications for palaeoenvironmental conditions and hydrocarbon generation potential. Marine Petroleum Geol. 48, p. 31-46.
(Tertiary coals from Mukah and Balingian coalfields in W Sarawak good source rock potential. Dominated by Type III kerogen and mixed Type II/III kerogens with HI values of 90-289 mg HC/g TOC. C coals thermally immature (lignite to sub-bituminous C rank), with huminite reflectance of 0.26-0.39%)

(Geothermal gradient database from well and temperature data of wells in Malay basin (101 wells, av. 51.8 °C/km), Sarawak basin (88 wells; av. 43.3 °C/km) and Sabah basin (54 wells; av. 30.5°C/km))

Hall, R. (2013)- Contraction and extension in northern Borneo driven by subduction rollback. J. Asian Earth Sci. 76, p. 399-411.
(online at: http://searg.rhul.ac.uk/pubs/hall_2013%20Borneo%20extension-rollback.pdf)
(Paleogene subduction of Proto-South China Sea ended with E Miocene collision of Dangerous Grounds/Reed Bank/N Palawan block and Sabah-Cagayan Arc. Much of N Borneo then became emergent, forming Top Crocker Unconformity. N-ward subduction of Celebes Sea initiated Sulu Sea backarc basin, followed by subduction rollback to SE; associated volcanic arc emerged briefly above sea level and collapsed in M Miocene. Rollback drove extension in N Borneo and Palawan. Two main extensional episodes (1) ~16 Ma, marked by Deep Regional Unconformity; (2) ~10 Ma, Shallow Regional Unconformity. Both episodes caused exhumation of deep crust, probably on low angle detachments, followed by granite magmatism. NW Borneo-Palawan Trough interpreted as flexural response to gravity-driven deformation of sediment wedge, caused by uplift on land that resulted from extension, with contribution of deep crustal flow)

Hall, R. (2015)- Trenches, troughs and unconformities; collision, contraction and extension: South China Sea, Borneo-Palawan and Sulu Sea. Geoscience Techn. Workshop, Tectonic evolution and sedimentation of South China Sea Region, Kota Kinabalu 2015, AAPG Search and Discovery Art. 90236, 3p. *(Extended Abstract)*

Hazebroek, H.P. & D.N.K. Tan (1993)- Tertiary tectonic evolution of the NW Sabah continental margin. In: G.H. Teh (ed.) Proc. Symposium on tectonic framework and energy resources of the Western margin of the Pacific Basin, Kuala Lumpur 1992, Bull. Geol. Soc. Malaysia 33, p. 195-210.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1993015.pdf)
(NW Sabah continental margin 6 tectono-stratigraphic provinces. Two main phases of Tertiary basin development: (1) pre-early M Miocene deep-marine clastic sedimentation; (2) post-early M Miocene clastic shelf/ slope deposition, prograding NW over unconformably underlying sediment wedge. NW Sabah Trough young feature, not Paleogene trench (Baram Delta prism masks Paleogene trench). Tectonic evolution: (1) Late Eocene-early M Miocene oblique subduction of S China Sea oceanic crust beneath NW Sabah; (2) Diachronous collision of S China Sea attenuated continental crust with Sabah and cessation of ocean-floor spreading in early M Miocene, led to uplift and erosion of accretionary prism (Deep Regional Unconformity); (3) Resumption of convergence between Borneo and NW Sabah Platform in middle Late Miocene, with formation of Shallow Regional Unconformity. E Sabah ophiolite complex continues into Palawan)

Hazebroek, H. P., D.N.K. Tan & J. M. Lamy (1992)- Tectonic evolution of the Northwest Sabah continental margin since Late Eocene. AAPG Int. Conf., Sydney 1992, Search and Discovery Art. 91015, p.
(Abstract only; see also Tan and Lamy 1990) (Four-stage tectonic evolution model of NW Sabah shelf (1) Late Eocene - early M Miocene subduction of S China Sea oceanic crust beneath Borneo, with creation of accretionary prism, (2) collision of S China Sea attenuated continental crust with Borneo in early M Miocene, leading to uplift and erosion of accretionary prism and creation of 'Deep regional unconformity', followed by M Miocene- early Late Miocene NW progradation over inboard belt;. (3) Cessation of active subduction in middle Late Miocene accompanied by major tectonic activity, with compressional deformation of Inboard Belt, creating 'Shallow Regional Unconformity';(4) In Outboard Belt and East Baram Delta, thick prograding wedge built out to NW from Late Miocene- Holocene. Late Pliocene deformation mainly in Outboard Belt and E Baram Delta)

Heller, J., D. Basuki, M. Choo, S. O ćConnor & R. Swarbrick (2014)- Using simple loading models to predict crestal pore pressures in Miocene carbonate exploration targets, Luconia, Sarawak. Proc. 38th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA14-G-169, 9p.
(C Luconia province in offshore Sarawak Basin with numerous Miocene- Recent carbonate build-ups, many with commercial hydrocarbons. Key risk for tall (up to 1km relief) buildups traps is mechanical seal failure, where pore pressure at crest of structure exceeds fracture strength of seal. Overpressure prediction model proposed based on sedimentation rates and stratigraphic ages)

(Sulu Sea marginal basin resulting from E Miocene intra-arc rifting. Early stages with explosive volcanic activity and rifting resulting in extensive Ayer, etc. olistostromes, corresponding to Ayer, Tungku and Kuamat, Garinono Fms. Uplift of Crocker Fm to W provide source for major quartz sands in SabahTanjong Fm and major NE flowing delta near Sandakan fed turbidites of deep Sulu Sea. Sabah ophiolite complex predates late early Miocene opening of Sulu Sea basin and represents Lower Cretaceous ocean floor on which arc was built. Rare metabasite with glaucophane)

Hutchison, C.S. (1994)- Melange on the Jerudong Line, Brunei Darussalam, and its regional significance. In: G.H. Teh (ed.) Petroleum geology Conf. 8, Bull. Geol. Soc. Malaysia 36, p. 157-161.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1994030.pdf)
(Large olistostrome deposit S along Jerudong Line, with sandstone blocks up to 3m diameter embedded in Setap Shale. Jerudong Line was Late Miocene submarine continental slope down which unconsolidated sands slumped W into deeper water part of Baram Delta)

Hutchison, C.S. (1996)- The ôRajang accretionary prismô and Lupar Lineô problems of Borneo. In: R.Hall & D. Blundell (eds.) Tectonic evolution of Southeast Asia, Geol. Soc., London, Spec. Publ. 106, p. 247-261.
(Rajang Group in Sarawak (and Embaluh Group in Kalimantan and equivalent rocks in Sabah, E Kalimantan) N-facing accretionary prism, composed of Cretaceous- Late Eocene turbiditic sediments, younging N-ward. Compressed into steeply S-dipping phyllite-quartzite complex (= M-Late Eocene Sarawak orogeny; collision

between Schwaner Mts Zone and Luconia-Balingian-Miri microcontinent). Unconformably overlain in N and S by M-U Eocene continental- neritic clastics. Sabah W Crocker Fm Oligocene turbidites more shaly in N, and nearshore in S. Several Miocene folding-uplift pulses. Provenance from uplifted U Cretaceous-Eocene of NE Kalimantan and E Sarawak. M-Late Miocene Crocker Fm uplift ('Sabah orogeny' = E-M Miocene;JTvG). Uplift ceased in Late Miocene. Paleocurrents show Upper Eocene basal sandstones provenance from metamorphosed Sibu Zone. Kalimantan Melawi and Mandai basins unconformably over flysch-belt. Basins not forearc, but formed after transformation of accretionary prism to collision complex landmass)

Hutchison, C.S. (2001)- Sundaland half-grabens of Sarawak; implications. Abstracts Petrol. Geol. Conf. Exhib. 2001, Paper 12, Warta Geologi (Newsl. Geol. Soc. Malaysia) 27, 5, p. 228-230. *(Abstract only)*
(Sundaland large continental peninsular landmass with half-grabens rifting from Late Eocene-Oligocene. Sarawak W of West Balingian Line (Tatau or Mukah Province) integral part of this landmass, with NW-SE Late Eocene- pre M Miocene grabens with up to 5km non-marine fill; marine inundation only after M Miocene sag. Similar half grabens simultaneously developed on uplifted Rajang Group of Sibu Zone (Rajang had become part of Sundaland after Late Eocene Sarawak Orogeny. Ketungau Basin of Kalimantan not unique. Sundaland Late Eocene half-grabens are intermontane basins, like Basin and Range province of W North America)

Hutchison, C.S. (2002)- Did the northwest Borneo Trough terminate at the West Baram line; what do the Miocene adakites/diorites indicate? Warta Geologi (Newsl. Geol. Soc. Malaysia) 28, 5, p. 250-251.
(NW Borneo Trough represents extinct plate margin and was active trench during spreading of S China Sea marginal basin, from anomalies 11 (31 Ma) to 5c (16 Ma)).

Hutchison, C.S. (2005)- Geology of North-West Borneo- Sarawak, Brunei and Sabah. Elsevier, Amsterdam, p. 1-421.
(Extensive review of Sarawak, Brunei, Sabah and N Kalimantan geology and stratigraphy)

Hutchison, C.S. (2010)- The North-West Borneo Trough. Marine Geology 271, 1-2, p. 32-43.
(NW Borneo Trough in deepwater Brunei-Sabah with melange wedge along SE margin, best explained as fossil trench-accretionary prism, preserved when subduction ceased in M Miocene with arrival of thinned continental crust at Benioff Zone, choking subduction and causing isostatic uplift of W Cordillera of Sabah. Overlain by undeformed Upper Miocene- Holocene drape. Alternative interpretation was a SW major NW-directed thrust Sheet System over autochthonous Dangerous Grounds terrane of attenuated continental crust of S China Sea passive margin. Enigmas remain in Palawan area, where trough position is bathymetrically obscure in places and position makes it impossible to derive Calamian micro-continent from continental Asia as required from its stratigraphy. In SW Trough terminates abruptly at W Baram Line. Trough contains several spectacular edifices, formerly suggested to be volcanoes or mud volcanoes but are drowned carbonate build-ups)

Hutchison, C.S. (2010)- Oroclines and paleomagnetism in Borneo and South-East Asia. Tectonophysics 496, p. 53-67.
(Oroclinal bending of Borneo is result of indentation and collision by continental Miri Zone- C Luconia Block in Eocene. Collision caused strong compression and uplift of Sibu Zone U Cretaceous- Eocene Rajang-Embaluh Gp turbidite basin, which is floored by oceanic crust of Proto South China Sea. No paleomagetic work on oroclinally bent Sibu Zone rocks in NW limb. Limited paleomagnetic support for required CCW rotation in NE limb. Previous syntheses emphasised CCW rotation or stable non-rotation of Borneo region as coherent entity, without internal deformation, ignoring oroclinal shape defined by geology of island)

Hutchison, C.S. (2011)- Oroclines and paleomagnetism in Borneo and South-East Asia. In: Petrol. Geol. Conf. Exhib. (PGCE 2011), Kuala Lumpur, Warta Geologi 37, 1, p. 39. *(Abstract only)*
(online at: https://gsmpubl.files.wordpress.com/2014/09/warta37_1.pdf)
(Oroclinal bending of Borneo resulted from indentation and collision of Miri Zone- C Luconia continental block of N Sundaland into S Sundaland (= Late Eocene 'Sarawak Orogeny'))

Hutchison, C.S., S.C. Bergman, D.A. Swauger & J.E. Graves (2000)- A Miocene collisional belt in north Borneo: uplift mechanism and isostatic adjustment quantified by thermochronology. J. Geol. Soc. London 157, p. 783-793.
(Subduction followed by underthrusting of continental lithosphere, driven by Oligocene-Miocene spreading in S China Sea, account for Sabah tectonic features. Isostatic rebound caused Late Miocene uplift of W Cordillera. Strata buried to 4-8 km, then rapidly exhumed and cooled at ~0.6mm/year. Rapid erosion supplied abundant clastics to Baram Delta, E lowlands and Sulu Sea. E Lowlands affected by Miocene Sulu Sea rifting)

(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1995a12.pdf)
(Study of 1989 Sarawak deepwater seismic transects. Two tectonostratigraphic provinces. North Luconia 7-8 km of Tertiary sediments, NNE-SSW trending extensional faults, buried hills and local forced folds. On E boundary NNE-SSW fault separates it from NW Sabah Platform with NE-SW trending rifts with only 2-4 km sediment. West Luconia Province up to 13 km of sediments, very thick post M Miocene, with E-W trending growth faults and slumps/ toe thrusts formed by gravity gliding. These overlie normal-faulted section at mid Miocene unconformity. Five sub-megasequences recognised)

Ismail, M.I. & R.B.A. Hassan (1999)- Tinjar province. In: Petronas (1999) The petroleum geology and resources of Malaysia, Chapter 16, p. 395-409.
(Geology and hydrocarbon of area onshore Sarawak with U Eocene- U Miocene sediments, uplifted and folded at end Early Miocene and Late Miocene. No discoveries so far)

Ismail, W.N.W, S.H. Tahir & Basir Jasin (2014)- Barremian-Aptian radiolaria from Chert-Spilite Formation, Kudat, Sabah. Warta Geologi 40, 3-4, p. 59-61.
(online at: www.gsm.org.my/products/702001-101643-PDF.pdf)
(Radiolarian chert in siliceous shale in ophiolitic rocks at Bukit Pangaraban, Kudat, E Sabah, with radiolarians dominated by Thanaria pacifica, Dictyomitra communis, Pseudoeucyrtis hanni and Podobursa typica, suggesting Barremian-Aptian (E Cretaceous) age. Radiolarian chert is from basalt association. Low CaO content suggests deposition below calcite compensation depth. Chert deposited on E Cretaceous oceanic crust and represent oldest rocks in Sabah)

Iyer, S.R., Ong Swee Keong, N. Asmah, F. Nazihah & Satyanarayana (2010)- An insight into the tectonic framework and structural evolution of a frontier area in Sarawak Offshore Basin, Malaysia. Petrol. Geosc. Conf. Exhib. (PGCE) 2010, Kuala Lumpur, p. 178-181. *(Extended Abstract)*
(Structural fabric off Sarawak characterized by strong overprint of NW-SE to N-S reactivated basement trend, over the older, less distinct, NE-SW trend. Post MMU tectonic setting: quiescent W half, separated by West Balingian zone, from an active wrench- tectonics-dominated E half. Timing of wrench movement shifted from Late Miocene in W to Recent in E)

Iyer, S.R., Ong Swee Keong, F. Nazihah & S.A. Abdullah (2012)- New perspective on evolution of northern provinces of offshore Sarawak Basin, Malaysia. AAPG Int. Conf. Exhib., Singapore 2012, Search and Discovery Art. 10482 (2013), 19p. *(Presentation package)*
(online at: www.searchanddiscovery.com/documents/2013/10482iyer/ndx_iyer.pdf)
(Basins offshore Sarawak initiated as Late Cretaceous (?)- Late Eocene intra-cratonic rifts on continental crust on foreland bulge (Phase I), creating N-S and NE-SW-trending half-grabens, dipping to E and SE. Gravity modeling results suggest 15-20 km thick attenuated continental crust. Extension continued, with opening of S China Sea in E Oligocene (Phase II), and subsequent drift phase up to early M Miocene. Well results suggest non-marine to transitional environment for Cycle I -Lower Cycle II, and outer neritic to bathyal for Cycle III. Regional uplift in late E Miocene- M Miocene, resulted in regional Middle Miocene Unconformity. Age of MMU younger towards E. Major NW-SE transtension close to MMU time along SW Luconia fault zone resulted in formation of W Luconia Trough. Late Miocene-Recent NE sag of basin led to a deep-water setting)

Iyer, S.R., H. Rosidah & A.S. Amar (2012)- Maturation of a new play concept in Northern Provinces of Offshore Sarawak Basin, Malaysia. Petrol. Geosc. Conf. Exh. (PGCE 2012), Warta Geologi 38, 2, p. 125-126.

Jasin, Basir, H. Sanudin Tahir & R.H.S. Abdul (1985)- Lower Cretaceous radiolaria from the Chert-Spilite Formation, Kudat, Sabah. Warta Geologi 11, 4, p. 161-162.
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm1985004.pdf)
(Brief paper on Lower Cretaceous radiolaria from chert above pillow lava in in Chert-Spilite Fm of N Sabah (ocean floor sediments). First paper to conclusively demonstrate Barremian age of basal radiolarites above ophiolite. Including several Tan Sin Hok 1927 species like Conosphaera tuberosa, Hemiaryptocapsa pseudopilula, Stiahocapsa pseudodecora and Archaeodictyomitra pseudoscalaris, suggesting possible Barremian- E Albian age)

Jasin, Basir, Sanudin Tahir & Z. Harun (1995)- Some Miocene planktonic foraminifera from Bidu-Bidu area, Sabah. Warta Geologi 21, 4, p. 241-246.
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm1995004.pdf)
(Garinono Fm in Bidu-Bidu area, C Sabah with chaotic melange/ debris flow deposits. Planktonic foraminiferal assemblage from melange mudstone matrix include Globigerinoides bisphericus and Praeorbulina sicana (N8, late E Miocene). Overlain by well bedded tuffaceous mudstone-sandstone sequence with Orbulina universa, O. suturalis and Globorotalia fohsi peripheroacuta (N10; early M Miocene). During M Miocene intense volcanic activity with widespread tuffaceous material in E Sabah)

Jasin, Basir, H.T. Sanudin & F.F. Tating (1991)- Late Eocene planktonic foraminifera from the Crocker Formation, Pun Batu, Sabah. Warta Geologi 17, 4, p. 187-191.
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm1991004.pdf)
(Red mudstone from Crocker Fm near Pun Batu, SW Sabah, rich in latest Eocene planktonic foraminifera, incl. Turborotalia cerroazulensis, Hantkenina alabamensis, Cribrokantkenina inflata, etc.)

Jasin, Basir & Selvarajah (1988)- Paleogene planktonic Foraminifera from Pulau Kalampunian Kecil, Sabah. Sains Malaysiana 17, 1, p. 99-113.

Jasin, Basir & Taj Madira Taj Ahmad (1995)- Some Paleogene planktonic foraminifera from the Lubok Antu melange, Sarawak, Malaysia. Warta Geologi 21, 3, p. 147-151.
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm1995003.pdf)
(13 species of planktonic foraminifera from mudstone matrix of Lubok Antu Melange of Lupar Valley, W Sarawak. Two assemblages:(1) early M Paleocene with Subbotina triloculinoides, S. velascoensis, Morozovella uncinata, M. trinidadensis, etc.; (2) M Eocene with Morozovella aragonensis, Acarinina bulbrooki, etc.. Blocks in melange include common Late Jurassic- Cretaceous radiolarian cherts)

Jasin, Basir & F. Tongkul (2000)- Fosil radiolaria daripada jujukan ofiolit Lembah Baliojong, Tandek, Sabah. In: Ibrahim Komoo & H.D. Tjia (eds.) Warisan Geologi Malaysia 3, LESTARI, UKM, p. 219-230.
('Radiolarian fossils in the ophiolite sequence in Baliojong Valley, Tandek, Sabah')

Jasin, Basir & F. Tongkul (2013)- Cretaceous radiolarians from Baliojong ophiolite sequence, Sabah, Malaysia. J. Asian Earth Sci. 76, p. 258-265.
(Baliojong ophiolite sequence Baliojong River in N Sabah consists of basalts, overlain by well-bedded cherts, mudstones and sandstones. Ophiolite sequence occurs as steeply-dipping, N-S oriented, overturned thrust slices in Cenozoic sediments. Two radiolarian assemblage zones in cherts: (1) Dictyomitra communis Zone (Barremian-Aptian) including Dictyomitra pseudoscalaris (Tan) and Pantanellium squinaboli (Tan) and (2) Pseudodictyomitra pseudomacrocephala Zone (Albian-Cenomanian). Cherts probably first sediment deposited on newly formed Cretaceous oceanic crust, intensely folded before deposition of Paleogene Crocker Fm)

Jennings, A.V. (1888)- Notes on the orbitoidal limestone of North Borneo. Geol. Magazine 5, 12, p. 529-532.
(Limestones of uncertain location, probably Silungen in Soubis and from Batu Gading, collected by Burls contains Discocyclina spp. and Asterocyclina, probably Eocene in age)

Johansson, M. (1999)- Facies analysis of the Plateau Sandstone (Eocene to Early Miocene?), Bako National Park, Sarawak, Malaysia. J. Asian Earth Sci. 17, p. 233-246.
(Sandstones near Kuching, W Sarawak, known as 'Plateau Sandstones', of possible Eocene- E Miocene age. Anomalous kerogen compositions, proximity of onlap surface and paleocurrent direction to NNE, suggest Bako Peninsula sands unrelated to Plateau Sst Fm in Klingang Range on Kalimantan border. New name Bako Sst. Very thick-bedded sst with lenses of conglomerates and sandy mudstones, formed in braided channel environment)

Johnson, H.D., J.W. Chapman & J. Ranggon (1989)- Structural and stratigraphic configuration of the Late Miocene Stage IVC reservoirs in the St. Joseph field, offshore Sabah, NW Borneo. Bull. Geol. Soc. Malaysia 25, p. 79-118.

(Bunguran (= deepwater Rajang Delta) and Sabah (= deepwater Baram Delta) Fold-thrust belts result from complex interplay between gravity-driven deformation and episodic regional thin-skinned compression driven by South China Sea tectonics along margin)

Jong, J., P. Barber, L.H. Chim, Q.T. Tran, H. Kusaka, K. Muramoto & R. Uchimura (2013)- The petroleum systems of onshore West Baram Delta, Northern Sarawak, Malaysia. In: Petroleum Geoscience Conf. Exhib. (PGCE 2013), Kuala Lumpur, O2, 4p. *(Extended Abstract)*
(Onshore part of W Baram Delta petroleum province in N Sarawak with two distinct petroleum system: (1) southern overmature gas system, sourced from deeply buried Eo-Oligocene basinal shales, charging wrench-induced traps like Engkabang Anticline; (2) permit-wide oil and gas system sourced from peak mature Mid-Late Miocene carbonaceous shales-coals in synclines, charging inversion and compressional fold structures. Expulsion and charge of traps started in Late Miocene and continues to present-day)

Jong, J., P. Barber, Q.T. Tran & R. Uchimura (2015)- The petroleum systems of onshore West Baram Delta, Northern Sarawak, Malaysia. Proc. SE Asia Petroleum Expl. Soc. (SEAPEX) Conf., Singapore 2015, 5.2, 4p. *(Extended Abstract + Presentation)*

(Onshore W Baram Delta petroleum province in N Sarawak with Eocene-Recent sediment succession, affected by three main deformation episodes: (1) late Cretaceous- Eocene (80-36 Ma) block faulting, with Eocene (rel. tight) platform carbonates on local highs (2) late Oligocene- M Miocene (30-20.5 Ma) wrench movement along West Baram-Tinjar Line, (3) M Pliocene- Recent (4.0-0 Ma) uplift and compression/inversion (e.g. Miri Anticline). With 2014 Adong Kecil West-1 discovery near Miri. Source rocks: (1) southern gas system from overmature Eo-Oligocene basinal shales, (2) northern oil-gas system from mature M-L Miocene carbonaceous shales/ coals in synclinal areas)

Jong, J. & S. Barker (2015)- Sequence stratigraphy, deformation history and gross deposition environmental study of deepwater Block 2F. In: Asia Petroleum Geoscience Conf. Exhib. (APGCE 2015), Kuala Lumpur, p. 323-327.
(Block 2F in Bunguran Trough, deepwater Rajang Delta area, off Sarawak in S China Sea. Trough evolved as tectonically-induced sag basin. Oldest known rocks shelfal clastics of E Miocene Cycles I/II, now buried >6000m. Late Miocene Cycle V ~3000m of slope and toe-of-slope deposits, overlain by Plio-Pleistocene sediments with turbiditic fairways forming main objectives in current exploration campaign)

Jong, J., S. Barker, F.L. Kessler & T.Q. Tan (2014)- The Sarawak Bunguran fold belt: structural development in the context of South China Sea tectonics. In: Proc. 8th Int. Petrol. Techn. Conf. (IPTC), Kuala Lumpur, 18197-MS, 30p.
(Bunguran Trough in offshore Sarawak Deepwater Block 2F with folded Neogene anticlines with reverse faults and thrusts in cores. Bunguran Fold Belt is deepwater setting of Rajang Delta/ W Luconia Delta, for which gravity sliding was advocated as mechanism of deformation. However, steep folds in anticline cores with mainly reverse faults and anticlines in zones of thicker sediment, suggest inversions of sediment depocentres by compressional tectonics. Foldbelt deformation driven by both gravity and regional compression)

Jong, J., S. Barker, F.L. Kessler & T.Q. Tan (2015)- One basin with several sediment sources: stratigraphic records of the Bunguran Trough, Central South China Sea. In: Tectonic evolution and sedimentation of South China Sea region, AAPG Workshop Kota Kinabalu, Search and Discovery Art. 30405, 7p. *(Ext. Abstract)*
(online at: www.searchanddiscovery.com/documents/2015/30405jong/ndx_jong.pdf)
(Bunguran Trough intra-continental deepwater basin in W Luconia Province, off Sarawak in S China Sea. Sag basin, where two major lineaments crossed. Oldest known rocks E Miocene shelfal clastics, now buried at >6000m, overlain by U Miocene Cycle V 3000m of slope and toe-of-slope deposits, overlain by distal muddy sediments of Muda Fm equivalent. All Pleistocene and older units underwent multiple deformations. Main Neogene sediment supply shifted from Natuna High to Rajang Delta, then back to Natuna area in Pliocene)

Jong, J., S. Barker, F.L. Kessler & T.Q. Tan (2017)- Basin with multiple sediment sources: tectonic evolution, stratigraphic record and preservation potential of the Bunguran Trough, South China Sea. Berita Sedimentologi 38, p. 5-48.
(online at: https://drive.google.com/file/d/0B35lLH-Cki2NV01LNEVCcGl2Z2M/view)
(Deepwater Bunguran Trough off Sarawak is intra-continental pull-apart basin in deepwater Rajang/West Luconia Delta province. Oldest stratigraphy shelf clastic deposits Late Oligocene Cycle I (= Gabus Fm of Natuna Basin), now buried to >7000m. Sediments sourced from: (1) Natuna Arch in Oligocene- E Miocene and Late Pliocene- Pleistocene (feldspatic and quartz-rich turbidites); (2) Rajang/ W Luconia Delta (Neogene) and (3) minor contributions from Dangerous Grounds/ N Luconia and C Luconia Platform areas to N and E)

Jong, J., H.A.B.M. Idris, P. Barber, F.L. Kessler, Tran Q. Tan & R. Uchimura (2017)- Exploration history and petroleum systems of the onshore Baram Delta, northern Sarawak, Malaysia. Bull. Geol. Soc. Malaysia 63 (Geol. Soc. Malaysia 50th Anniversary Issue 1), p. 117-143.
(online at: www.gsm.org.my/products/702001-101705-PDF.pdf)
(Review of onshore Baram Delta province in N Sarawak, with M Eocene- Holocene succession and 1910 Miri oilfield discovery. Three episodes of deformation: (1) Late Cretaceous- Eocene (79.5-36 Ma) block faulting, (2) Late Oligocene- M Miocene (30-20.5 Ma) wrench movement and folding; (3) M Pliocene (4 Ma)- Holocene uplift and compressional folding. Two major anticlinal trends: Engkabang-Karap in S, Miri-Asam Paya in N. Two distinct petroleum systems: (1) overmature gas in S, sourced from deep Eo-Oligocene basinal shales with

reworked terrestrial organic matter. Earlier oil charge probably in Oligocene before late basin reversal; (2) oil and gas system from peak-mature M-L Miocene carbonaceous shales and coals in synclines, charging inversion compressional structures along N Miri-Asam Paya anticlinal trend, and Miocene at Engkabang-Karap Anticline. Expulsion and charge started in Late Miocene and is continuing to present-day. Exploration results of Eo-Oligocene carbonate play disappointing. Onshore Baram Delta still contains attractive plays)

Thickness 1.5- 7.5 m. Now at different elevations (14-38m altitude) and appear to be block-faulted, implying tectonic movements in Holocene)

Kessler, F.L. & J. Jong (2014)- The origin of Canada Hill- a result of strike-slip deformation and hydraulically powered uplift at the Pleistocene/Holocene border? Bull. Geol. Soc. Malaysia 60 (C.S. Hutchison Memorial Issue), p. 35-44.
(online at: https://gsmpubl.files.wordpress.com/2015/04/bgsm20140041.pdf)
(Canada Hill in centre of Miri, Sarawak, roofed by Pleistocene/Holocene terrace deposits, implying very young uplift of complex anticline. Structure explained by strike-slip deformation, in conjunction with diapyric pillow of Setap Fm clay)

Kessler, F.L. & J. Jong (2015)- Incision of rivers in Pleistocene gravel and conglomeratic terraces: further circumstantial evidence for the uplift of Borneo during the Neogene and Quaternary. Bull. Geol. Soc. Malaysia 61, p. 49-57.
(online at: www.gsm.org.my/products/702001-101676-PDF.pdf)

(Incised Pleistocene gravel beds and conglomerates common feature of Baram, Limbang and Temburong drainage systems in NW Sarawak and Brunei. Incision from 9-76 m likely result of strong precipitation, combined with ongoing uplift. Conglomerates almost exclusively from Lower Miocene Meligan Sst, and deposited in nested fluvial terraces. Uplift may be ongoing present day)

Kessler, F.L. & J. Jong (2015)- Tertiary uplift and the Miocene evolution of the NW Borneo shelf margin. Berita Sedimentologi 33, p. 21-46.
(online at: www.iagi.or.id/fosi/files/2015/09/BS33-Marine-Geology-of-Indonesia-II-R1.pdf)
(In NW Borneo transition from muddy M Miocene shelf to unusually sandy one attributed to (1) rise of Borneo part of Sundaland in M-L Miocene, caused by tectonic compression and (2) availability, through erosion of Rajang/Crocker sand source. E-M Miocene Cycle III 'Setap Shale' in Baram Delta rel. lean in sand. First massive regional sand pulse in Baram Delta and Sabah during Cycle IV (Serravallian), post-MMU/DRU times. Continued sand supply established shelf edge that remained almost stationary throughout Mid Cycle V)

Kessler, F.L. & J. Jong (2016)- Northwest Sarawak: a complete geologic profile from the Lower Miocene to the Pliocene covering the Upper Setap Shale, Lambir and Tukau Formations. Warta Geologi 41, 3-4, p. 45-51.
(online at: https://gsmpubl.files.wordpress.com/2016/03/warta41_3-4.pdf)
(~1000m thick outcrop section along 3-4 km of new Miri- Long Lama road (NW Sarawak), with two major regional unconformities: (1) M Miocene Unconformity (MMU) between U Setap Shale and Lambir Fm, and (2) Mio-Pliocene angular unconformity between folded Lambir rocks and unfolded Tukau Fm)

Kessler, F.L. & J. Jong (2016)- Paleogeography and carbonate facies evolution in NW Sarawak from the Late Eocene to the Middle Miocene. Warta Geologi 42, 1-2, p. 1-9.
(online at: https://gsmpubl.files.wordpress.com/2016/08/warta42_1_2.pdf)
(After Paleocene-E Eocene Sarawak Orogeny (~40-36 Ma) shallow shelf developed in NW Sarawak, which included Luconia/Tinjar terranes and rimmed recently emerged Rajang Gp hinterlands. Late Eocene benthic foraminiferal limestone banks and ramps developed on sheltered shoals. By E-M Oligocene carbonate deposition slowed. Second episode of carbonate deposition in E-M Miocene, with small coral-algal bioherms)

Khamis, M.A., J. Jong & S.M. Barker (2018)- Deformation profile analysis of a deepwater toe-thrust structural trend- Implications on structural kinematics and sedimentary patterns. Bull. Geol. Soc. Malaysia 65, p. 1-12.
(online at: https://gsmpubl.files.wordpress.com/2018/08/bgsm201801.pdf)
(Offshore NW Sabah deepwater fold-thrust belt with tightly folded and thrusted Miocene-Pleistocene sediments, resulting from interaction between gravitational and compressional forces. Shallow-Regional Unconformity (SRU) separates pre- and post-kinematic phases. Structuration and deformation history of "L-B-P" structures varied along structural trend and play role in controlling sediment fairway distribution patterns)

Khamis, M.A., J. Jong, S.M. Barker, S.A. Abdullah & Y. Watanabe (2018)- Deformation profile analysis of deepwater Sabah toe-thrust structural trends- observations on structural kinematics and implications on sedimentary fairway distribution patterns. Offshore Technology Conf. Asia, Kuala Lumpur, OTC-28338-MS, 22p.
(Deepwater NW Sabah toe-thrust dominant NW-SE oriented compression from Early-Late Miocene, during closing of proto-S China Sea and subsequent opening of S China Sea. Deformation history varied along structural trends. Genetic link between structural growth and sediment fairways)

Khan, A.A., W.H. Abdullah, Meor H. Hassan & K. Iskandar (2017)- Tectonics and sedimentation of SW Sarawak basin, Malaysia, NW Borneo. J. Geol. Soc. India 89, 2, p. 197-208.
(SW Sarawak basin S-ward sloping basement characterized by passive margin tectonics: Triassic extension, Cretaceous transpression and Oligo-Miocene compression. Deeper basin zone between Schwaner Mts block to S and SW Sarawak basin to N. E-W trending Cretaceous carbonate platform in SW Sarawak basin signify shelf zone where shallow marine sedimentation progressed during Cretaceous transpression. Late Cretaceous- E Eocene Kayan Sst unconformable on Cretaceous Pedawan Fm. NW-SE trending Oligo-Miocene continental volcanic arc. Back-arc extension prevailed in Oligo-Miocene. SW Sarawak basin two sub-basins (Senibong in W, Kuching in E), with wide range of transpressive features. Sri Aman marginal sea-basin characterized by oceanic assemblages, ophiolite, serpentinite and pillow basalt)

Kho, C.H. (1968)- Bintulu Area, Central Sarawak, East Malaysia. Explanation of sheet 3/113/13. Geol. Survey Malaysia, Borneo region, Report 5, p. 1-83.
(1:50,000 scale geologic map of area around Bintulu town, C Sarawak, with primary purpose evaluation of Miocene coal beds. Oldest beds up to 14,000' thick Nyalau Fm marine-paralic clastics with zone Te4- Te5 (latest Oligocene- E Miocene) foraminifera limestones with Miogypsinoides and Heterostegina borneensis and Lepidocyclina (Eulepidina), etc. Overlain by E Miocene Setap Shale Fm (or lateral equivalent of Nyalau Fm.; Hutchison 2005). Folded in E Pliocene)

King, R.C., G. Backe, C.K. Morley, R.R. Hillis & M.R.P. Tingay (2010)- Balancing deformation in NW Borneo: quantifying plate-scale vs. gravitational tectonics in a delta and deepwater fold-thrust belt system. Marine Petroleum Geol. 27, 1, p. 238-246.
(GPS show 4-6 mm/yr of NW Borneo plate-scale shortening, not accommodated by plate-scale structures. Total shortening observed in Baram delta toes does not balance against active extension in delta top; additional shortening therefore attributed to plate-scale shortening across NW Borneo produced by far-field compression)

King, R.C., R.R. Hillis, M.R.P. Tingay & A.R. Damit (2010)- Present-day stresses in Brunei, NW Borneo: superposition of deltaic and active margin tectonics. Basin Research 22, 2, p. 236-247.
(Two present-day stress provinces previously identified across Baram Delta System: (1) inner shelf inverted province with margin-normal (NW-SE) max. horizontal stress orientation and (2) outer shelf extension province with margin-parallel (NE-SW) max. horizontal stress. Borehole breakouts from 12 petroleum wells confirm margin-normal max. horizontal stress orientations of inverted province (mean max. hor. stress orientation of ~117°). NW Borneo continental margin currently tectonically quiescent)

Kob, M.R.C. & M.Y. Ali (2008)- Regional controls on the development of carbonates in East Natuna Basin and Luconia area. Proc. 32nd Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA-08-G-078, 6p.
(E Natuna basin- Luconia platforms off NW Borneo between areas of subsidence/ faulting in N and compressional tectonics in S. Extensive development of carbonates in Early -Late Miocene. Late Oligocene- E Miocene extension in Luconia and nearby areas, followed by episodic compression in M Miocene. Areas near main uplifted region in E and SW dominated by clastics, carbonates thrived on rifted margin in W. Similar setting in E Natuna. Subsequent compression resulted in inversion and folding, with uplift of parts of E Natuna-Luconia region. Folds formed sites for latest M-Late Miocene carbonate growth. Sea level rise at base Pliocene drowned most of carbonate in region except few buildups in NW, which still thrive today)

Kob, M.R.C. & M. Mohamed (1995)- Chronostratigraphy of Miocene turbiditic sequence of Sabah Basin from nannofossil assemblages. In: G.H. Teh (ed.) Proc. AAPG-GSM Int. Conf. Southeast Asian basins: oil and gas for the 21st century, Kuala Lumpur 1994, Bull. Geol. Soc. Malaysia, p. 143-163.
(online at: www.gsm.org.my/products/702001-100955-PDF.pdf)
(Offshore Sabah Basin is Neogene trench-associated basin filled with progradational cycles of marine and coastal sediments. Age-determinations of M-L Miocene strata through quantitative nannofossil analysis more reliable than foraminifera due to floods of reworked forms. Dominant indigenous assemblages differentiated from reworked assemblages through quantitative analysis)

Kob, M.R.C., J. Norazlina, A.H. Samsudin & A. Mansor (2015)- Tectono-stratigraphic evolution and hydrocarbon prospectivity of the North Tarakan Basin, Onshore Sabah. In: Asia Petrol. Geoscience Conf. Exhib. (APGCE), Kuala Lumpur, 26151, 5p. *(Extended Abstract)*
(SE Sabah N Tarakan basin Paleogene-Neogene sediments evolved as foreland basin in relation to thrusting of Rajang fold-thrust belt (accretionary complex). Basin uplifted and eroded in stages in E Miocene-Pliocene. E-M Miocene Tanjong, Kapilit and Kalabakan Fms potential oil and gas resources. Conventional traps due to thrust and wrench tectonics. Late Eocene unconformity between Sapulut and Labang Fms= 'Sarawak Orogeny')

Kocsis, L., A. Briguglio, A. Roslim, H. Razak, S. Coric & G. Frijia (2018)- Stratigraphy and age estimate of Neogene shallow marine fossiliferous deposits in Brunei Darussalam (Ambug Hill, Tutong district). J. Asian Earth Sci. 158, p. 200-209.
(Outcrops of sandstones-clays at Ambug Hill in NE Brunei with layers rich in marine fossils. Calcareous nannoplankton of Late Tortonian- E Messinian (NN11) age, confirmed by Sr-isotope age from bivalves (8.3- 6.2 Ma). Overlain by emersion surface, possibly tied to Me1 (7.25 My) or Me2 (5.73 My) sequence boundary)

Kocsis, L., H. Razak, A. Briguglio & M. Szabo (2018)- First report on a diverse Neogene cartilaginous fish fauna from Borneo (Ambug Hill, Brunei Darussalam. J. Systematic Palaeontology, 2018, 30p. *(online preview)*

(Diverse Late Miocene cartilaginous fish fauna from Brunei (~6.5-8 Ma). Chondrichthyan fish remains 24 taxa of selachians (sharks, etc.) and batoids (rays). Shark fauna dominated by Carcharhiniformes, including teeth extinct giant Otodus (Megaselachus) megalodon shark. Batoids dominated by Myliobatiformes. Dominance of carcharhinid sharks and small rays suggests shallow marine, coastal paleoenvironment)

Kon'no, E. (1968)- Some Upper Triassic species of Dipteridaceae from Japan and Borneo. J. Linnean Soc. London, Botany, 61, 384, p. 93-105.
(Description of Cuxthropteris (=Clathropteris) meniscoides from near SW border of Sarawak, southernmost occurrence of Dipteridaceae flora of SE Asia in Borneo in Upper Triassic)

Konôno, E. (1972)- Some Late Triassic plants from the Southwestern border of Sarawak, East Malaysia. In:T. Kobayashi & R. Toriyama (eds.) Geology and palaeontology of Southeast Asia, University of Tokyo Press, 10, p. 125-178.
(Plants from beds near basal conglomerates of Halobia-bearing coaly series near Krusin, SW Sarawak. Probably Late Carnian age. 15 species from Sadong Fm, now called'Krusin flora'. With Neocalamites, Clathropteris miniscoides, Dictyophyllum cf. nilssoni, Cladophlebis spp., Todites, etc. Belongs to Dictyophyllum-Clathropteris floral province of E Asia/ SW Pacific, without any European or North Asian floral elements, and similar to Norian Tonkin Flora of N Vietnam. No stratigraphy details (Hutchison 2005: associated in same formation Carnian-Norian bivalves Halobia and Monotis salinaria and sands derived from Serian Volcanics) (Krusin flora classified as Carnian age, and 'East Asian floristic zone', similar to 'Yamaguti Flora' of Japan, by Dobruskina 1994))

Koopmans, B.N. & P.H. Stauffer (1968)- Glacial phenomena on Mount Kinabalu, Sabah. In: Geological papers 1966, Malaysian Geol. Survey, Borneo region, Bull. 8, p. 25-35.
(Evidence of Pleistocene glacial erosion above 12,000' at on Mt. Kinabalu (elev. 4100m/ 13,455'). Glaciated, with ice cap of ~5.4 km2 in Pleistocene until about 10,000 years ago. Two Pleistocene glaciations, but no clear moraines)

Kosa, E. (2012)- Pore-pressure and subsurface-plumbing patterns in Central Luconia; Offshore Sarawak, Malaysia. In: Delivering value: realising exploration & development potential, Proc. Petrol. Geosc. Conf. Exh. (PGCE 2012), Kuala Lumpur, 4p. *(Extended Abstract)*
(Hydraulically blown traps and overpressure-related operational issues still encountered in C Luconia carbonate buildup play. Predictive pressure model proposed based on identification of five principal pressure domains, characterised by different drainage mechanisms)

Kosa, E. (2013)- The rivers of Luconia: the effects of sea-level lowstands on the stratigraphy of a mixed carbonate/clastics province; Miocene- Present, Offshore Sarawak, NW Borneo. In: Proc. Petrol. Geosc. Conf. Exh. (PGCE 2013), Kuala Lumpur, 5p. *(Extended Abstract)*

(C Luconia gas-producing province with ~250 carbonate build-ups, now mostly covered by clastics. Clastics historically interpreted as marine, pro-delta sediments deposited over drowned carbonates, but re-interpreted as stacked delta lobes with paleo-coastlines extending basinward of most Luconia build-ups. This study suggests evidence for fluvial and other erosional geomorphology and links this to hydrocarbon habitats, carbonate-clastic interactions and reservoir/seal distribution. Fluvial processes exerted major control on carbonate inception inM Miocene, and on hydrocarbon-retention capacity of clastic overburden)

Kosa, E. (2013)- Wings, mushrooms and Christmas trees: insights from carbonate seismic geomorphology into the evolution of Central Luconia. AAPG Int. Conv. Exhib., Singapore 2012, Search and Discovery Art. 50783, 51p. *(Presentation and Abstract; see also full paper Kosa et al. (2015))*
(online at: www.searchanddiscovery.com/documents/2013/50783kosa/ndx_kosa.pdf)
(C Luconia gas province off Sarawak, NW Borneo with >200 Miocene-Recent carbonate build-ups identified. Interpretation of carbonate geomorphology from seismic varied through time. Prevalent model of evolution of C Luconia infers 'maximum transgression' initiating carbonate growth in M Miocene, followed by progressive burial of province under Borneo-sourced clastic deltas in Late Miocene. Hydrocarbon columns in C Luconia tend to be short and terminate at intersections of carbonate edifices with clastic sequence boundaries. New model of clastic stratigraphy proposed, of stacked delta-lobes punctuated by exposure and/or flooding surfaces and evolving contemporaneously with carbonates)

Kosa, E. (2015)- Sea-level changes, shoreline journeys, and the seismic stratigraphy of Central Luconia, Miocene-present, offshore Sarawak, NW Borneo. Marine Petroleum Geol. 59, p. 35-55.
(C Luconia province of Sarawak Basin with>200 M Miocene- Recent carbonate build-ups. Clastic sediments around/ between carbonate build-ups interpreted as stacked low-relief deltas, which frequently prograded beyond area of carbonate build-ups. Deltaic topsets juxtaposed against carbonate build-ups hydrocarbon migration routes. Most carbonate reservoirs underfilled; hydrocarbon columns limited to youngest onlapping sequence)

Kosa, E., A. Hafrez, K. Boey, A. Azhar & G. Wee (2012)- Sequence stratigraphy of clastic overburden of the Miocene carbonate gas province in Central Luconia, Offshore Sarawak, NW Borneo: implications for hydrocarbon-retention capacity. In: Int. Petrol. Techn. Conf. (IPTC), Bangkok 2012, IPTC 14578, p. 1208-1213.
(C Luconia, off NW Borneo, mature gas province with >45TCF gas discovered in Miocene carbonate build-ups. Most commercial discoveries in carbonate platforms, but remaining prospectivity mostly in pinnacle-shape carbonates, where commercial volumes require long hydrocarbon columns)

Kosa, E., G.M.D. Warrlich & G. Loftus (2015)- Wings, mushrooms, and Christmas trees: the carbonate seismic geomorphology of Central Luconia, Miocene-present, offshore Sarawak, Northwest Borneo. American Assoc. Petrol. Geol. (AAPG) Bull. 99, 11, p. 2043-2075.
(see also Kosa (2013). C Luconia province of Sarawak Basin off NW Borneowith extensive Miocene-Holocene carbonate buildupse up to 2km thick and with complex seismic geomorphologies. Intermittent carbonate and siliciclastic deposition governed by oscillating sea level and variable siliciclastic input. Location of buildups with respect to deltaic facies and seismic expressions of marginal carbonate strata, locally known as wings, used here to classify carbonate seismic geomorphologies)

Kosaka, H. & K. Wakita (1975)- Geology and mineralization of the Mamut mine, Sabah, Malaysia. Mining Geology 25, 132, p. 303-320. *(In Japanese, with English summary)*
(online at: https://www.jstage.jst.go.jp/article/shigenchishitsu1951/25/132/25_132_303/_pdf)
(Mamut mine in NW Sabah, ~65 km E of Kota Kinabalu, is first porphyry copper mine in Borneo. Commercial operation started in 1975. Ore reserves ~178 Mtons of 0.476 percent copper. Area occupied by U Cretaceous and Tertiary flysch type sediments and igneous rocks. In mineralized area sedimentary rocks mainly Paleocene-Eocene sandstone, with serpentinized ultrabasic rocks and adamellite porphyry intrusions, possibly parts of large batholith under area, represented by Mt. Kinabalu. Late Miocene- E Pliocene K-Ar ages. Size of main adamellite porphyry intrusive ~800x 300m. Ore zone max. width 450m, length 800m and depth 200m)

Kosaka, H. & K. Wakita (1978)- Some geologic features of the Mamut porphyry copper deposit, Sabah, Malaysia. Economic Geology 73, 5, p. 618-627.
(Mamut porphyry copper-gold deposit of Paleocene- Upper Miocene age one of many mineralized centers in NW-SE trending tectonic zone in Sabah, N Borneo. Copper mineralization associated with K-rich adamellite porphyry intrusion. Wall rocks consist of serpentinite and clastic sediments. See also Imai (2000))

Kosters, M., P.F. Hague, R.A. Hofmann &d B.L. Hughes (2008)- Integrated modeling of karstification of a Central Luconia Field, Sarawak. In: Int. Petroleum Techn. Conf. (IPTC 2008), Kuala Lumpur, IPTC 12327, 9p.
(Some carbonate fields in C Luconia gas province karstified, as demonstrated by severe drilling losses. Largest gas field (1969 discovery, ~175km NNW of Bintulu, producing since 1987) is elongate Miocene buildup. Seismic study suggests extensive dendritic karst network in zones 3 and 4, mainly in C and E parts of field. Overlying zone 2.3 part of transgressive systems tract with rel. poor porosities and form field-wide baffle)

Krebs, W.N. (2011)- Upper Tertiary chronosequence stratigraphy of offshore Sabah and Sarawak, NW Borneo, Malaysia: a unified scheme based on graphic correlation. Bull. Geol. Soc. Malaysia 57, p. 39-46.
(online at: http://geology.um.edu.my/gsmpublic/BGSM/bgsm57/bgsm2011006.pdf)

Krebs, W.N. & A. van Vliet (2009)- The Middle Miocene Unconformity (MMU): neither Middle Miocene nor unconformity? In: Programme and abstracts Petroleum Geology Conf. Exh., Kuala Lumpur 2009, Geol. Soc. Malaysia, Paper 16. *(Abstract only)*
(online at: http://geology.um.edu.my/gsmpublic/PGCE2009/Draft/Old/Geology%20Papers%20v.0.1.pdf)
(Middle Miocene Unconformity of N Borneo/ S China Sea not true unconformity, but end of late E Miocene extension around 'oceanic' core of S China Sea. Crests of fault-blocks experienced minor submarine erosion. Bako-1 and Mulu-1 wells drilled on paleo-highs, reveal age of MMU is late E Miocene)

Krol, L.H. (1927)- Palaeozoicum (?) in Sarawak en Britsch-Noord Borneo. De Mijningenieur 8, p. 113-115.
(On the age of coal-bearing rocks from Sarawak: initially believed to be of Late Paleozoic age (Tennison Woods, 1885, based on presumed presence of Vertebraria and Phyllotheca), but more likely of Tertiary age)

(Review of offshore Sarawak hydrocarbon province, with 4 main fields (Temana, Bayan, D18, D35) in Late Oligocene- E Miocene deltaic clastics)

Madon, M., Cheng L.Kim & R. Wong (2013)- The structure and stratigraphy of deepwater Sarawak, Malaysia: Implications for tectonic evolution. J. Asian Earth Sci. 76, p. 312-333.
(History of N Luconia Province, Sarawak deepwater area, related to tectonic history of S China Sea. Sarawak Basin initiated as foreland basin as result of collision of Luconia block with Sarawak (Sarawak Orogeny), with deep foreland basin ('flysch') phase in Late Eocene-Oligocene, followed by 'molasse' phase of shallow marine shelf progradation to present day. E Miocene Unconformity caused by relative uplift and submarine erosion between ~19-17 Ma, with 500-2600m of missing section, equivalent to 8-10 My time gap. EMU extends over entire NW Borneo margin and related to Sabah Orogeny which marks cessation of sea-floor spreading in S China Sea and collision of Dangerous Grounds block with Sabah. Sarawak basin part of remnant ocean basin that closed by oblique collision along NW Borneo margin. Closure started in Late Eocene in Sarawak and moved progressively NE into Sabah until M Miocene)

Madon, M. & A. Hadi Abd Rahman (2007)- Penecontemporaneous deformation in the Nyalau Formation (Oligo-Miocene), Central Sarawak. Bull. Geol. Soc. Malaysia 53, p. 67-73.
(online at: www.gsm.org.my/products/702001-100502-PDF.pdf)
(Outcrops of Late Oligocene- E Miocene Nyalau Fm in Tg. Similajau and Bintulu areas show common penecontemporaneous deformation (thrusts/ folds, slumps, etc.), indicating tectonic controls on sedimentation in Sarawak foreland basin)

Madon, M. & R.B.A. Hassan (1999)- Tatau Province. In: The petroleum geology and resources of Malaysia, Chapter 17, Petronas, Kuala Lumpur, p. 413-426.
(Review of offshore Sarawak Tatau hydrocarbon province, with gas-oil fields in non-marine U Oligocene- Lw Miocene clastics and M-U Miocene carbonates. Characterized by NNW trending E Miocene normal faults)

Madon, M. & R.B.A. Hassan (1999)- West Luconia Province. In: The petroleum geology and resources of Malaysia, Chapter 18, Petronas, Kuala Lumpur, p. 428-439.
(W Luconia Province in W part of Sarawak continental shelf. Major Oligocene- Miocene West Luconia Delta system developed between C Luconia carbonate platform in E and Natuna Platform in W. Underexplored area, with hydrocarbon shows in U Miocene)

Madon, M., K.M. Leong & Azlina Anuar (1999)- Sabah Basin. In: The petroleum geology and resources of Malaysia, Chapter 22, Petronas, Kuala Lumpur, p. 501-542.
(NW Sabah Basin mainly offshore with >12km of early M Miocene and younger sedimentary basin, formed after uplift and exhumation of underlying Oligocene- E Miocene and older unmetamorphosed turbidites of

'Crocker fold-thrust belt', with upper and lower Rajang units separated by major Late Eocene unconformity. Pre-and post lower M Miocene sediments separated by 'Deep Regional Unconformity'. Basin includes Baram Delta complex, which extends west into Sarawak and Brunei. Several oil-gas fields, incl. Tembungo, Barton, Erb South, Ketam, etc.)

Madon, M., J. Norazlina, A. Ayub, K.S.M. Nor, S.M. Najmi, I.A. Zamzamie & A. Yusof (2015)- Structural evolution of the NW Sabah deepwater fold and thrust belts and its implication for hydrocarbon prospectivity. Asia Petrol. Geosc. Conf. Exhib. (APGCE), Kuala Lumpur, p. 317-321. *(Extended Abstract)*
(NW Sabah deepwater fold-thrust belt may be viewed as deformed sedimentary fill of Sabah Trough foreland basin. Deformation along margin appears diachronous, increasing N-wards. Mainly forward/seaward-breaking thrusts, while landward-verging backthrusts in N resulted in complex interference fold-thrust structures)

(Seismic stratigraphic study of Late Miocene hydrocarbon-bearing Stage IVD turbidite sequence around Tembungo field, offshore W Sabah. Turbidite sequence, characterised by oblique seismic reflection pattern, deposited in sedimentary bypass system tract as result of wrench-related uplift of Bunbury-St. Joseph area)

Mat Zin, Ismail C. (1994)- Dent Group and its equivalent in the offshore Kinabatangan area, East Sabah. In: G.H. Teh (ed.) Petroleum Geology Conf. VIII, Bull. Geol. Soc. Malaysia 36, p. 127-143.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1994028.pd)
(Dent Peninsula in E Sabah with thick Miocene deltaics (Dent Group), unconformably overlying Oligocene - E Miocene (and older?) Segama Gp conglomeratic rocks with ultrabasic, etc. boulders. Onshore Dent Peninsula Togopi Fm mainly marls, Ganduman Fm delta plain deposits grading to shallow marine deltaic and marine eastward, argillaceous Sabahat Fm marine deposit) Three major uplifts of regional significance occurred in E Miocene (deformation of Segama Gp), Late Miocene and Late Pliocene times)

Mat Zin, Ismail C. (1996)- Tertiary tectonics and sedimentation history of the Sarawak basin, East Malaysia. Ph.D. Thesis Durham University, p. 1-277.
(online at: http://etheses.dur.ac.uk/5198/1/5198_2651.PDF)
(Seismic stratigraphic study of offshore Sarawak Basin. Seven regional unconformities in Tertiary sedimentary succession of Sarawak Basin, some related to eustatic sea-level falls; others probably tectonic in origin. Sarawak Basin best explained as result of NW-SE trending right lateral fault movement in Oligocene- Pliocene. Rapid subsidence in early stage of basin formation. Tectonism in region combination of strike-slip movements and counter-clockwise rotation of Borneo in Oligo-Miocene. Five major dextral strike-slip lineaments: Igan-Oya Line, Mukah Line, W Balingian Line, Tinjar Line and W Baram Line)

Mat Zin, Ismail C. (1997)- Tectonics evolution and sedimentation history of the Sarawak Basin. In: G.H. Teh (ed.) Petroleum Geology Conference '96, Kuala Lumpur, Bull. Geol. Soc. Malaysia 41, p. 41-52.
(online at: www.gsm.org.my/products/702001-100871-PDF.pdf)
(Seismic stratigraphy of offshore Sarawak Basin shows 7 unconformities in Tertiary section. Development of basin started in late Oligocene, with deposition along coastline in NW-SE direction (along ~W Balingian Line; parallel to major structural lineaments) and became oriented to present day NE-SW direction in Late Miocene. Basin formed as result of NW-SE trending right-lateral fault movement in Late Oligocene-Miocene. Deposition and preservation of coastal plain and shallow marine sediments continued in E, while W area remained as high until Late Miocene)

Mat Zin, Ismail C. (1997)- Subsidence history of Sarawak Basin. In: Proc. ASCOPE 97 Conf. Challenges and opportunities in the 21st century, 1, p. 107-127.

Mat Zin, Ismail C. (1998)- Subsidence nature of a strike-slip related basin: an example learned from the Sarawak Basin. In: G.H. Teh (ed.) Petroleum geology conference 1997, Bull. Geol. Soc. Malaysia 42, p. 63-83.
(online at: www.gsm.org.my/products/702001-100855-PDF.pdf)
(Subsidence profile of Sarawak Basin suggests basin formed by strike-slip tectonism, not foreland lithospheric flexure by subduction of S China Sea oceanic crust beneath NW Sarawak. Burial history curves for wells show rapid early subsidence followed by later phase of slower subsidence, indicative of rift-type tectonic origin. These are followed by compressional basin inversion events or continued with thermal subsidence similar to rift basin profile. Stretching factors and heat-flow show consistent with strike-slip tectonics)

Mat Zin, Ismail C. (1999)- Tertiary tectonic model of North-West Borneo. In: G.H. Teh (ed.) Proc. 9th Reg. Congress Geology, Mineral and Energy Resources of SE Asia (GEOSEA ô98), Kuala Lumpur 1998, Bull. Geol. Soc. Malaysia 43, p. 417-432.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1999042.pdf)
(Sarawak Basin dominated by NE-SW strike-slip tectonism. Onshore Lupar Melange Lupar Melange in SW Sarawak ~20 km wide, composed of blocks in sheared pelitic matrix with Lower Eocene microfauna; chert blocks with E-M Cretaceous radiolaria. Commonly interpreted as subduction melange, but may beformed by strike-slip tectonics. Eight other NW-SE trending strike slip zones identified on- and offshore Sarawak)

Mat Zin, Ismail C. (2000)- Stratigraphic position of the Rangsi Conglomerate in Sarawak. In: G.H. Teh et al. (ed.) Geol. Soc. Malaysia Ann. Conf. 2000, Pulau Pinang, p. 131-136.
(online at: https://gsmpubl.files.wordpress.com/2014/10/agc2000_18.pdf)
(Rangsi conglomerate that outcropping in Tatau Horst area in Sarawak long regarded as (Late Eocene) basal unit of Tatau Fm. Seismic stratigraphic suggests Rangsi conglomerate much younger than Tatau Fm, possibly equivalent to Balingian Fm of Late Miocene age. 'Tatau Horst' not extensional horst, but positive flower structure, formed as result of Miocene transpressional strike-slip episode)

(Seismic facies study of Late Miocene/Early Pliocene Lingan Fan complex of turbidite fans offshore NW Sabah. Fan system divided into 4 seismic sequences. Turbidite systems first pond into higher, more proximal basins and reach more distal basins by successive fill and spill processes. Four seismic facies identified)

Mohamed, A., A.H. Abd Rahman and M. S. Ismail (2015)- Sedimentary facies of the West Crocker Formation North Kota Kinabalu-Tuaran Area, Sabah, Malaysia. Journal of Physics, Conference Series 660, 012004, IOP Publishing, p. 1-6.
(online at: http://iopscience.iop.org/article/10.1088/1755-1315/30/1/012004/pdf)
(Sedimentology study of new outcrops in W Crocker Fm in Sabah suggests deposition in sand-rich submarine fan setting, with inner fan channel-levee complex, mid-fan channelised lobes, and outer fan facies)

Mohamed, Idris & O.C Meng (1992)- Sequence stratigraphy of Tertiary sediments offshore Sarawak (Balingian and Luconia provinces). In: Symposium on the Tectonic framework and energy resources of the western margin of the Pacific Basin. Warta Geologi 18, 6, p. 277-278.

Mohammad, A.M. & R.H.F. Wong (1995)- Seismic sequence stratigraphy of the Tertiary sediments, offshore Sarawak deepwater area, Malaysia. In: G.H. Teh (ed.) Proc. AAPG-GSM Int. Conf. 1994, Southeast Asian basins; oil and gas for the 21st century, Bull. Geol. Soc. Malaysia 37, p. 345-361.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1995a26.pdf)
(Sarawak deepwater seismic sequence stratigrapy study identified eight sequences, grouped into four supersequences A, B, C and D, tied to regional tectonic events of S China Sea. Higher order sequences also interpreted from paleontologic, lithologic, paleofacies data and GR-logs from four wells. Four main seismic facies, ranging from non-marine to deepmarine. Seismic facies maps for Oligocene-Lower Miocene Ss C indicate all four facies, overall transgressive stacking, and NW-SE trending paleoshoreline. M Miocene-Recent Ss D suggests mainly outer shelf- deep marine facies and E-W trending paleoshoreline)

Mohammad, Y.b. Ali. & P. Abolins (1999)- Central Luconia Province. In: Petronas (1999) The petroleum geology and resources of Malaysia, p. 371-391.

McMonagle, L.B. (2008)- Scleractinian reef-coral diversity in the Oligocene of Sabah, Borneo.
(online at: http://londonevolutionarynetwork.files.wordpress.com/2010/02/2008conferencebook.pdf)
(Abstract only. Modern Indo-W Pacific characterised by highest global species diversity in reef corals. Reef-coral fauna collected from Oligocene patch-reef facies in Gomantong Fm of Sabah, Malaysia (late Early to early Late Oligocene) doubled number of coral species previously known from Oligocene of Borneo, and suggests apparent paucity of Paleogene corals from SE Asia could be result of sampling bias. Coral diversification had occurred by Early Oligocene, rather than at Oligocene/Miocene boundary)

McMonagle, L.B., P. Lunt, M.E.J. Wilson, K.G. Johnson, C. Manning & J. Young (2011)- A re-assessment of age dating of fossiliferous limestones in eastern Sabah, Borneo: implications for understanding the origins of the Indo-Pacific marine biodiversity hotspot. Palaeogeogr. Palaeoclim. Palaeoecology 305, p. 28-42.
(Shallow marine limestones rel. rare onshore N Borneo and show punctuated development, in area underlain by oceanic crust and dominated by deep marine sedimentation. Re-dating of limestones in E Sabah: (1) Lower Kinabatangan Lst mid-Oligocene (coral-rich, larger foram zone Te1, nannofossil zone NP24, Sr isotope ages 28.8-27.6 Ma); (2) Gomantong Lst Early Miocene (LBF zone Te5/earliest Tf1, Sr age 21.0 Ma); (3) Togopi Limestone with Alveolinella quoyi and abraded Calcarina (Pliocene-Pleistocene; Sr age 1.72 Ma)

Morgan, A.B. (1974)- Chemistry and mineralogy of garnet pyroxenites from Sabah, Malaysia. Contrib. Mineralogy Petrology 48, p. 301-314.
(Garnet pyroxenites ('eclogites') and corundum-garnet amphibolites from Dent Peninsula of E Sabah occur as exotic blocks in Late Miocene slump breccia deposit of Segama Gp. Bulk composition and mineralogy similar to garnet pyroxenite lenses within ultramafic rocks. Estimated T and P for pyroxenites ~850° C and ~19 kbar (= mantle depth, ~65km?)

Morley, C.K. (2003)- Outcrop examples of mudstone intrusions from the Jerudong anticline, Brunei Darussalam and inferences for hydrocarbon reservoirs. In: P. van Rensbergen et al. (eds.) Subsurface sediment mobilization, Geol. Soc., London, Spec. Publ. 216, p. 381-394.
(Mudstone intrusions in Jerudong area represent natural hydraulic fractures developed above mobile mudstone diapir sourced from M Miocene Setap Fm. Intrusion geometries influenced by pre-existing normal faults)

Morley, C.K. (2007)- Interaction between critical wedge geometry and sediment supply in a deep-water fold belt. Geology 35, 2, p. 139-142.
(On low angle dips of surface and basal detachment faults of Late Miocene–Holocene deep-water fold-and-thrust belt of offshore NW Borneo)

Morley, C.K. (2009)- Geometry of an oblique thrust fault zone in a deepwater fold belt from 3D seismic data. J. Structural Geol. 31, 12, p. 1540-1555.
(Late Pliocene-Recent growth of 12 km long, deepwater anticline at distal margin of Baram Delta Province)

Morley, C.K. (2009)- Growth of folds in a deep-water setting. Geosphere 5, 2, p. 59-89.

(Seismic data of deep-water area off NW Borneo provide picture of interaction between sedimentary processes on continental slope and growth of major folds over time period of ~3.5-5 Ma)

Morley, C.K. & S. Back (2008)- Estimating hinterland exhumation from late orogenic basin volume, NW Borneo. J. Geol. Soc., London, 165, 1, p. 353-366.
(Miocene- recent sediment volumes for Baram Deltaic Province estimated. Volume restoration onto sediment source area determined exhumation of ~5 km from 17 Ma- Recent. Denudation for M Miocene, Late Miocene and Pliocene- Recent proceeded at similar rates. Initial uplift of central Borneo attributed to buoyancy of thinned continental crust that jammed subduction zone under NW Borneo in E Miocene. Absence of decay in erosion rates from M Miocene-Recent suggests additional uplift possibly related to slab detachment)

Morley, C.K., S. Back, P. van Rensbergen, P. Crevello & J.J. Lambiase (2003)- Characteristics of repeated, detached, Miocene-Pliocene tectonic inversion events in a large delta province on an active margin, Brunei Darussalam, Borneo. J. Structural Geol. 25, p. 1147-1169.
(Baram Delta province evolved in M Miocene- present day from foreland basin to shelf margin. Episodic folding events caused uplift of hinterland, delta progradation and inversion of gravity-related faults. Region best understood as development of W-verging thrust belt in M Miocene foreland basin with major folds forming in M Miocene. Onshore thrust and inversion features dominantly N-S-trending and began activity in M Miocene. In Late Miocene (7.5 Ma) NE-SW inversion folds developed. Continuation of deformation into Pliocene largely confined to offshore; onshore N-S structures not reactivated in Pliocene)

Morley C.K. & M. Burhannudinnur (1997)- Anatomy of growth fault zones in poorly lithified sandstones and shales: implications for reservoir studies and seismic interpretation: part 2, Seismic reflection geometries. Petroleum Geoscience 3, 3, p. 225-231.
(Seismic reflection data across growth faults off NW Borneo show many of small-scale fault geometries recognized in outcrop can also be interpreted on seismic data. Some fault zones single fault plane; others up to 1km wide bundles of overlapping fault planes connected by hard and soft linkage geometries)

Morley, C.K., P. Crevello & Z.H. Ahmad (1998)- Shale tectonics and deformation associated with active diapirism: the Jerudong Anticline, Brunei Darussalam. J. Geol. Soc., London, 155, p. 475-490.
(Jerudong anticline of Brunei outcrop example of multiple phases of diapir growth and interaction with country rock. N-S-trending anticline overlies high-angle transpressional basement fault zone. Deformation history: (1) M Miocene E-W to NE-SW-trending growth faulting and shale-diapir growth; (2) Late Miocene- E Pliocene transpression. Continued uplift and erosion elevated overpressured horizons to where hydraulic fracturing reached surface and Holocene-age mud volcanoes developed)

Morley, C.K., R. King, R. Hillis, M. Tingay & G. Backe (2011)- Deepwater fold and thrust belt classification, tectonics, structure and hydrocarbon prospectivity: a review. Earth-Science Reviews 104, p. 41-91.

Olave-Hoces, S. (2006)- Controls on isolated carbonate platform evolution and demise, Central Luconia province, South China Sea. M.Sc. Thesis Texas A&M University, College Station, p. 1-85.
(online at: http://repository.tamu.edu/bitstream/handle/1969.1/ETD-TAMU-1795/OLAVE-HOCES-THESIS.pdf)
(Many isolated carbonate platforms in C Luconia in M-Late Miocene. Flooding at ~16.5 Ma initiated near-simultaneous carbonate sedimentation. Five growth stages. SE C Luconia platforms thicker and larger, reflecting greater subsidence to SE. First platforms drowned in E at ~12.5-9.7 Ma, affected by siliciclastic sediments and high local subsidence. Platforms drowned later (~6.3-5.5 Ma) caused by rapid sea-level rise and local subsidence. C Luconia carbonate platforms drowned earlier (latest Late Miocene) than E Natuna platforms (E Pliocene))

Omang, S.A.K. (1993)- Petrology, geochemistry and structural geology of the Darvel Bay Ophiolite, Sabah, Malaysia. Ph.D. Thesis Royal Holloway, University of London, p. *(Unpublished)*

Omang, S.A.K. (1995)- Petrology and geochemistry of the mantle-sequence peridotite of the Darvel Bay Ophiolite, Sabah, Malaysia. Bull. Geol. Soc. Malaysia 38, p. 31-48.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1995004.pdf)
(Mantle-sequence peridotites of Darvel Bay Ophiolite mainly depleted harzburgites. Less depleted (refractory) mantle than harzburgites of Oman, Papuan and Halmahera ophiolites and represent supra-subduction zone (SSZ) ophiolite type)

Omang, S.A.K. (1996)- Sub-ophiolite metamorphic rocks in the Tungku area, Lahad Datu, eastern Sabah, Malaysia; origin and tectonic significance. In: G.H. Teh (ed.) Petroleum geology conference, Kuala Lumpur 1995, Bull. Geol. Soc. Malaysia 39, p. 51-64.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1996006.pdf)
(Sub-ophiolite metamorphic garnet amphibolites (clasts in late E Miocene- M Miocene melange) formed at high P-T and interpreted as derived from metamorphic sole below Darvel Bay Ophiolite Complex, formed during subduction of ocean crust and emplacement of ophiolite complex. Garnet amphibolites were oceanic crust MORB tholeiites, metamorphosed in upper mantle and deformed and recrystallised with mylonitic textures in amphibolite facies. K/Ar age of 76± 21 Ma (Cretaceous- Eocene!) coincides with Late Cretaceous-Paleogene age of subduction beneath Darvel Bay Ophiolite inferred from stratigraphic evidence)

Omang, S.A.K. (1996)- Petrology and geochemistry of the volcanic rocks associated with the Darvel Bay Ophiolite, Lahad Datu, eastern Sabah, Malaysia. In: G.H. Teh (ed.) Petroleum geology conference, Kuala Lumpur 1995, Bull. Geol. Soc. Malaysia 39, p. 65-80.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1996007.pdf)

(At least three unrelated volcanic rock groups in ophiolitic terrain of Darvel Bay area. Group I and II may be related to oceanic crust formation, Group III to M Miocene volcanic arc activity of Dent Peninsula)

Omang, S.A.K. & A.J. Barber (1996)- Origin and tectonic significance of the metamorphic rocks associated with the Darvel Bay Ophiolite, Sabah, Malaysia. In: R. Hall & D.J. Blundell (eds.) Tectonic evolution of SE Asia, Geol. Soc. London, Spec. Publ. 106, p. 263-279.
(Banded hornblende gneiss, amphibolite and schists form lenses in 8 km wide belt in Darvel Bay Ophiolite Complex, representing gabbros, plagiogranites, basaltic dykes, basaltic volcanics and cherts formed at spreading ridge in supra-subduction zone environment, deformed at high T- low P along transform fault. Garnet pyroxenites and amphibolites found as clasts in Miocene volcanic agglomerates formed at high-P, and derived from metamorphic sole formed during ocean crust subduction and emplacement of ophiolite complex)

Omang, S.A.K., M.M. Faisal & S.H. Tahir (1994)- The Kudat Ophiolite Complex, northern Sabah, Malaysia- field description and discussion. Warta Geologi (Newsl. Geol. Soc. Malaysia) 20, 5, p. 337-346.
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm1994005.pdf)
(Scattered M Jurassic- E Cretaceous ophiolitic rocks in Kudat Fault Zone, N-most Sabah, here named Kudat Ophiolite Complex. Represents dismembered ophiolite sequence, with most components of ophiolite present: sheared and brecciated serpentinite, plagiogranite, doleritic to basaltic dykes and submarine pillow basalt overlain by radiolarian chert with Lower Cretaceous radiolaria (Basir Jasin et al. 1985). May represent supra-subduction zone ophiolite type (= Kinabalu Suture of Tjia 1988))

Omang, S.A.K., W.A.W. Mohamed & S.H. Tahir & S.A. Rahim (1992)- The Darvel Bay ophiolite complex, SE Sabah, Malaysia- preliminary interpretations. Warta Geologi 18, 3, p. 81-88.
(Darvel Bay ophiolite complex of E Sabah consists of ultramafic (mantle peridotite and ultramafic cumulate), gabbro (gabbroic rocks, amphibolites and plagiogranites) and volcanic-sedimentary units (basaltic lavas and Cretaceous radiolarian cherts). Complex bounded by E-M Miocen melanges to N and S, with blocks of ophiolite. Complex interpreted as part of the oceanic crust segment which lay between Sundaland craton and the Philippines archipelago and was obducted onto Sabah in Late Paleogene to Neogene time)

Omang, S.A.K. & S.H. Tahir (1995)- Cretaceous and Neogene lavas of Sabah; origin and tectonic significance. Bull. Geol. Soc. Malaysia 38, p. 21-30.
(online as: www.gsm.org.my/products/702001-100928-PDF.pdf)
(Cretaceous Telupid basalt low-K tholeiitic lava or "boninitic suite", formed in response to intra-oceanic subduction. As subduction proceeded, magma composition changed to calc-alkaline suite (high-K Neogene Tungku and Tanjung Batu andesites). Volcanics evolution starts with oceanic island arc, where supra-subduction zone extension led to genesis of tholeiitic/ boninitic lava (Telupid basalt), followed by volcanic arc (Tungku andesite), followed by arc-splitting, as extension continued, Sulu Sea marginal basin formed. Partial closing of Sulu Sea caused S-ward subduction beneath older arc and formation of Tanjung Batu andesite)

(online at: http://www.gsm.org.my/products/702001-100559-PDF.pdf)

(Half-Graben sub-province in W Luconia, offshore Sarawak, characterised by NNW trending, SW-dipping extensional faults, creating sub-basins within half-grabens during M Miocene. Syn-rift carbonates at base of half-graben drowned as result of rapid graben subsidence and influx of clastics. M Miocene fluviomarine sediments filled half-grabens. Rifting ended at start of Late Miocene. Post-rift sediments two main hiatuses: U Miocene (~10.6 Ma) and Lower Pliocene (~5.6 Ma). Miocene-Pliocene boundary last major deformation, with faulted anticlinal structures in NW area, attributed to wrench-related inversion of extensional faults)

Sia, S.G. & W.H. Abdullah (2011)- Concentration and association of minor and trace elements in Mukah coal from Sarawak, Malaysia, with emphasis on the potentially hazardous trace elements. Int. J. Coal Geology 88, 4, p. 179-193.
(On hazardous elements in coal from Mukah field, which is enriched in As, Cr, Cu, Pb, Sb, Th, and Zn. Field with 12 coal seams in U Miocene Balingian Fm (E Miocene?; see Sia et al. 2014), which is unconformably overlain by E Pliocene Begrih Fm. Balingian Fm with brackish water forams Ammodiscus, Glomospira, Haplophragmoides, Trochammina)

Sia, S.G. & W.H. Abdullah (2012)- Geochemical and petrographical characteristics of low-rank Balingian coal from Sarawak, Malaysia: its implications on depositional conditions and thermal maturity. Int. J. Coal Geology 96-97, p. 22-38.
(Geochemical and coal petrographical analyses of low-rank U Pliocene Balingian coal from Sarawak. Characterised by high moisture, low ash and low sulphur contents. Low ash and sulphur content, together with lack of epiclastic partings indicate coal deposition in ombrotrophic raised bogs)

Sia, S.G. & W.H. Abdullah (2012)- Enrichment of arsenic, lead, and antimony in Balingian coal from Sarawak, Malaysia: modes of occurrence, origin, and partitioning behaviour during coal combustion. Int. J. Coal Geology 101, p. 1-15.
(Balingian Coal from U Pliocene Liang Fm in Sarawak highly enriched in As, Pb and Sb and vaporized and released into atmosphere during coal combustion. Enrichment may be related to nearby Sb-As mineralization. Liang Fm unconformably overlies Lower Pliocene Begrih Fm in N and Eocene Belaga Fm in S)

Sia, S.G., W.H. Abdullah, Z. Konjing & A.M. Koraini (2014)- The age, palaeoclimate, palaeovegetation, coal seam architecture/mire types, paleodepositional environments and thermal maturity of syn-collision paralic coal from Mukah, Sarawak, Malaysia. J. Asian Earth Sci. 81, p. 1-19.
(online at: https://umexpert.um.edu.my/file/publication/00004125_105774.pdf)
(Mukah coal in Balingian Fm previously assigned Late Miocene age, but abundance of Casuarina pollen associated with Dacrydium, Stenochlaena palustris, Florschuetzia levipoli and Stenochlaena areolaris indicate palynozone PR9, Early Miocene, i.e. during collision between Luconia- Dangerous Grounds Block with Borneo. Coal with common detrohuminite without enrichment of liptinite group macerals. Low sulphur content and evidence from palynomorphs in seams show coal was deposited in freshwater mires with little or no marine influence. Fauna present in host rock formation suggests brackish-water deposition)

Sia, S.G., W.H. Abdullah, Z. Konjing & J. John (2014)- Floristic and climatic changes at the Balingian Province of the Sarawak Basin, Malaysia, in response to Neogene global cooling, aridification and grassland expansion. Catena 173, p. 445-455.
(Increased seasonality or reduced rainfall as result of Neogene global cooling and aridification in onshore Balingian Province, but everwet climates persisted. Flora in region changed from predominantly Kerangas forest in Ey Miocene to species-rich peat swamp forest in Pliocene)

Sperber, C.M. (2009)- The thermotectonic development of Mount Kinabalu, Sabah, Malaysia. Ph.D. Thesis Royal Holloway, University of London, p. *(Unpublished)*
(Mount Kinabalu is 4095m high post-orogenic granitic intrusion, emplaced far from active plate boundaries at ~8 Ma. Thermochronological study suggests exhumation rates of ~0.40 mm/yr for central zone and ~0.60 mm/yr for marginal zone of igneous body)

Staub, J.R., H.L. Among & R.A. Gastaldo (2000)- Seasonal sediment transport and deposition in the Rajang River delta, Sarawak, East Malaysia. Sedimentary Geology 133, p. 249-264.

(Description of sedimentary processes in Rajang Delta, NW Borneo, and variations in deposition between wet and dry seasons)

Staub, J.R. & J.S. Esterle (1993)- Provenance and sediment dispersal in the Rajang River delta/ coastal plain system, Sarawak, East Malaysia. Sedimentary Geology 85, p. 191-201.
(Rajang delta in embayment formed by folded Mesozoic and Cenozoic sediments of C Borneo Massif. Alluvial valley floodplain, abandoned tidally flushed delta plain and actively accreting rectilinear delta/coastal plain. 50-80% of surface area covered by peat 1-20m thick. Margins of thick, domed peat deposits interfinger with and are overlain by root-penetrated siliciclastic sediments)

Staub, J.R. & J.S. Esterle (1994)- Peat-accumulating depositional systems of Sarawak, East Malaysia. Sedimentary Geology 89, p. 91-106.
(Prograding coastal depositional systems of Sarawak contain domed peat-accumulating environments in which low-ash, low-sulfur peats are being deposited in areas of clastic sedimentation. Depositional systems are as large as 11,400 km2, individual peat deposits >20m thick and 1000 km2 in area. Basal high-ash, high-sulfur, degraded peats overlain by low-ash, low-sulfur, well preserved peats)

Staub, J.R. & R.A. Gastaldo (2003)- Late Quaternary sedimentation and peat development in the Rajang River Delta, Sarawak, East Malaysia. In: F.H. Sidi et al. (eds.) Tropical deltas of Southeast Asia; sedimentology, stratigraphy, and petroleum geology. Soc. Sedimentary Geology (SEPM), Spec. Publ. 76, p. 71-87.
(Thick, domed peat deposits on Rajang delta tide-influenced alluvial valley and coastal plain. NE-striking shoreline terrace sands along landward margin of delta and coastal plain and gravel outcrops in alluvial valley expression of VIIa/ 125 ka highstand surface. Lignite near present coast at 80m depth represents IIIb highstand surface, indicating 40m of subsidence in last 40 ka. Gravel dominates base of incised-valley fill 10km wide-45m thick and overlain by fining-upward succession with tidally influenced upper part. Interfluve areas in landward half of NE delta plain and adjacent coastal plain with >10m Recent peat deposits on Pleistocene began accumulating between 7.3- 5.8 ka as rate of sea-level rise slowed. Seaward half of NE delta plain, delta front, and prodelta up to 40m thick seaward-thickening wedge, accumulated in last 5 ka, with basal gravel lag over rooted alluvial soil, overlain by delta-front and prodelta clays- silts, delta-front distributary-mouth sands and shoreline sands. Young (<5 ka), thin (<10m) peat on top of wedge in this part of delta plain)

(C-14 dating of oyster in raised coral limestone on Sipangao island 21' above high tide ~28,000 BP or older. On Danawan island coral cliffs >40' high)

Tamura, M. (1973)- Two species of lower Cretaceous *Parvamussium* from Kyushu, Japan, and Sarawak, Borneo. In: T. Kobayashi & R. Toriyama (eds.) Geology and palaeontology of Southeast Asia, University of Tokyo Press, 11, p. 119-124.
(Lower Cretaceous pectinid bivalve from Sarawak, S of Kuching. Also report perisphinctid ammonite from Bau series black shale, probably Berriasella or Microanthoceras indicating Tithonian-Berriasian age)

Tamura, M. & C. Hon (1977)- *Monotis subcircularis* Gabb from Sarawak, East Malaysia. In: T. Kobayashi et al. (eds.) Geology and Palaeontology of Southeast Asia, University of Tokyo Press, 18, p. 29-31.
(Late Triassic thin-shelled bivalve Monotis subcircularis found at Kuap, Sarawak. Identified as M. subcircularis, but more likely Monotis (Eomonotis) according to Silberling (1985))

Tamura, M. & C. Hon (1977)- Upper Jurassic bivalves from the Kedadom formation of Sarawak, Malaysia. In: T. Kobayashi & R. Toriyama (eds.) Geology and palaeontology of Southeast Asia, University of Tokyo Press, 18, p. 33-47.
(Kedadom Limestone Fm of W Sarawak rich in bivalves (Nuculana, Grammatodon, Somapecten, Lucina, Neoburmesia, etc.) show Callovian or Kimmeridgean to Berriasian age and related to Torinosu fauna on Pacific side of Japan (Kobayashi 1978, Hayami 1984) (similar to Vogel (1896, 1900) faunas from W Kalimantan?; also viewed as 'Torinosu-type fauna' by Tamura 1959; JTvG))

Tan, D.N.K. (1975)- Preliminary notes on the melange in the Lupar Valley. Annual Report Geol. Survey of Malaysia 1974, p. 219-228.

Tan, D.N.K. (1978)- Lower Cretaceous age for the chert in the Lupar Valley, West Sarawak. Warta Geologi 4, 6, p. 173-176.
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm1978006.pdf)
(Radiolaria assemblages identified by Pessagno from 5 exotic chert blocks in Lubok Antu melange of Lupar Valley, W Sarawak. Believed to be same as radiolaria studied by Hinde in Molengraaff (1902) from cherts in adjoining Upper Kapuas Valley in NW Kalimantan. Radiolaria studied by Pessagno indicate Early Cretaceous age, most likely Valanginian-Barremian (incl. Thanaria conica, Parvacingula spp., Pantanellium spp, Archaeodictyomitra, etc.)

Tan, D.N.K. (1979)- Lupar Valley, West Sarawak; Explanation of sheets 1-111-14, 1-111-15, and 1-111-16. Geol. Survey Malaysia Report 13, p. 1-159.
(Hutchison 2005: Lupar Line complex composed of imbricated U Cretaceous flysch with paleocurrents SW to NE (Lupar Fm), chaotic melange (Lubok Antu melange with E-M Eocene microfauna in matrix) and ophiolitic rocks (Pakong mafic complex: gabbro and pillow basalts))

Tan, D.N.K. (1982)- The Lubok Antu melange, Lupar Valley, West Sarawak: a Lower Tertiary subduction complex. Bull. Geol. Soc. Malaysia 15, p. 31-46.
(online at: www.gsm.org.my/products/702001-101188-PDF.pdf)
(Lower Tertiary Lubok Antu melange in W Sarawak 10.5 km wide in Lupar Valley, extending SE into Kalimantan. S of melange is U Cretaceous Lupar Formation = Danau Complex of Molengraaff (1902), with turbidite flow directions to NE. N of melange is Pakong mafic complex with overturned pillow lavas dipping steeply to NE. Melange contains of blocks of Lower Cretaceous (Valanginian-Barremian) radiolarian chert, mid-Cretaceous Orbitolina limestone, U Cretaceous greywacke and slate, Paleo-Eocene limestone with Distichoplax, Discocyclina and Nummulites, calcareous shale, mudstone, sandstone, basalt, spilite, gabbro and serpentinite in pervasively sheared pelitic matrix, locally with E Eocene foraminifera and nannofossils. Also recognition of low-grade prehnite-pumpellyite facies metamorphics. Geotectonic setting is Late Cretaceous- E Tertiary SW-dipping subduction of oceanic crust under West Borneo continental basement)

Tan, D.N.K. (1983)- Nomenclature of the Upper Cretaceous-Tertiary molasse deposits of West Sarawak. Annual Report Geol. Survey of Malaysia 1981, p. 348-355.
(Introduction of name Plateau Sandstone, used earlier in Kalimantan, to massive molasse deposits in W Sarawak by Liechti et al. (1961) caused much confusion. Some sands assigned to this should be 'Kayan Sst')

Tan, D.N.K. (1984)- Palaeocurrents in the Tertiary sedimentary deposits in western Sarawak. Bull. Geol. Soc. Malaysia 17, p. 258-264.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1984013.pdf)
Tertiary fluvial-deltaic sediments from 7 localities in W Sarawak investigated for paleocurrent indicators. Local mean directions to NW, N, NE, NNE and ESE suggest provenance of these rocks is Carboniferous-Permian and Mesozoic sedimentary, igneous and metamorphic rocks of present Bau-Kuching-Serian area)

Tan, D.N.K. (1986)- Palaeogeographic development of West Sarawak. In: G.H. Teh & S. Paramananthan (eds.) Proc. 5th Reg. Congress Geology, Mineral and Energy Resources of SE Asia (GEOSEA V), Kuala Lumpur 1984, 1, Bull. Geol. Soc. Malaysia 19, p. 39-49.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1986004.pdf)
(Four paleogeographic maps of W Sarawak: Carbo-Permian, Triassic, Jurassic-Cretaceous and Lower Tertiary. Carbo-Permian data limited. M-L Triassic Sadong Fm mixed continental- shallow marine deposits and Serian Volcanics. Early Jurassic orogeny/ uplift, feeding Late Jurassic-Cretaceous Kedadom and Pedawan Fms, and offshore deep-sea pelagic deposits. By Early Tertiary most of W Sarawak uplifted; intermontane basins with Silantek Fm, Kayan Sst and Plateau Sst)

Tan, D.N.K., B.A.R. Abdul Hadi, A. Azlina, B. Boniface & K.T. Chow (1999)- West Baram Delta. In: Petronas (1999) The petroleum geology and resources of Malaysia, Ch. 13, p. 293-341.
(Baram Delta is NW prograding delta system since M Miocene. Onshore Brunei exploration resulted in discovery of one large field (Miri,1910) and 27 unsuccessful wells. Offshore Brunei and Sabah 11 oil-gas discoveries by Shell between 1955-1988. Additional fields discovered in 1990's. Structures dominated by gravity tectonics (rotated fault blocks with growth faults. Oils generally light, low sulfur, derived from landplant material)

Tan, D.N.K. & J.M. Lamy (1990)- Tectonic evolution of the NW Sabah continental margin since the Late Eocene. Bull. Geol. Soc. Malaysia 27, p. 241-260.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1990027.pdf)
(NW Sabah Shelf tectono-stratigraphic provinces. Four tectonic stages: (1) Late Eocene- early M Miocene subduction of proto-S China Sea oceanic crust under Borneo; (2) early M Miocene collison of S China Sea continental crust with Borneo, with uplift and erosion of accretionary prism and 'Deep Regional Unconformity'; (3) cessation of subduction in M-L Miocene accompanied by compressional deformation associated with deep-seated N-S shear zones in inboard belt (4) Late Miocene-Holocene: inboard belt stable and eroding, outboard belt E Baram Delta, prograding to NW)

Tate, R.B. (1970)- Tektites in Brunei. Brunei Museum J. 2, 2, p. 253-259.
(Tektites from Jerudong Fm near Brunei coast dated as ~730,000 yrs old. Originated from large M Pleistocene Australasian tektite shower (but assoociated with 30,000 year old wood, so tektites possibly reworked into younger younger terrace deposits?))

Tate, R.B. (1976)- Palaeo-environmental studies in Brunei. Proc. SE Asia Petroleum Expl. Soc. (SEAPEX), Singapore, 3, p. 102-124.
(Measured sections of Brunei Neogene deltaic deposits with interpretations of paleoenvironments)

(Present-day stress in Tertiary Baram Delta exhibits range of values that reflect NW Borneo active margin (situated underneath the basin) and local stresses generated within delta)

Tingay, M.R.P., R.R. Hillis, C.K. Morley, R.E. Swarbrick & S.J. Drake (2005)- Present-day stress orientation in Brunei: a snapshot of prograding tectonics in a Tertiary delta. J. Geol. Soc. London 162, p. 39-49.
(Baram Delta on active margin. Structures margin-parallel gravity tectonics and margin-normal transpressive tectonics associated with active margin. Maximum horizontal stress margin-normal (NW-SE) in proximal parts of basin and margin-parallel (NE-SW) in outer shelf. Rotations result of 'deltaic' and 'basement-associated' tectonic regimes that 'prograde' basinwards. Proximity of active margin resulted in uplift and inversion of hinterland that forced delta system to prograde rapidly. Zone of active deltaic growth faulting 'prograded' as delta rapidly prograded across shelf. After uplift and delta progradation, old growth faults of inner shelf ceased being active and successively reactivated by similarly 'prograding' margin-normal inversion front)

Tingay, M.R.P., R.R. Hillis, C.K. Morley, R.E. Swarbrick & S.J. Drake (2005)- ôProgradingô tectonics in Brunei: regional implications for fault sealing. In: Alaska Rocks 2005, The 40th U.S. Symp. Rock Mechanics (USRMS): Rock mechanics for energy, mineral and infrastructure development in the Northern Region, Anchorage, ARMA/USRMS 05-785, 14p.
(online at: www.asprg.adelaide.edu.au/asm/papers/tingay2005b.pdf)

(Baram Delta province of Brunei built on active margin. Structures are result of both margin-parallel gravity-driven deltaic tectonics and margin-normal transpressive tectonics associated with active margin. Breakouts and DITFs observed in 19 wells suggest maximum horizontal stress oriented margin-normal (NW-SE) in proximal parts of basin and margin-parallel (NE-SW) in distal region. Margin-normal σHmax direction perpendicular to strike of Miocene-Pliocene normal growth faults, suggesting ~90° rotation over time. All major fields located in inner shelf region of Brunei where faults not optimally aligned for present-day reactivation and seal breach)

Tingay, M.R.P., R.R. Hillis, C.K. Morley, R.E. Swarbrick & E.C. Okpere (2003)- Pore pressure/ stress coupling in Brunei Darussalam; implications for shale injection. In: P. van Rensbergen et al. (eds.) Subsurface sediment mobilization, Geological Soc., London, Spec. Publ. 216, p. 369-379.
(Shale dykes, diapirs and mud volcanoes common in Brunei. Outcrop examples show shale intruded along faults and tensile fractures. Changes in pore pressure are coupled with changes in total minimum horizontal stress, so rocks can sustain greater pore pressure prior to failure than predicted)

Tingay, M.R.P., R.R. Hillis, C.K. Morley, R.E. Swarbrick & E.C. Okpere (2003)- Variation in vertical stress in the Baram Basin, Brunei: tectonic and geomechanical implications. Marine Petroleum Geol. 20, p. 1201-1212.
(Vertical stress determined in 24 fields in Baram Basin, using density log and checkshot velocity data. Basin shows variation in vertical stress gradient between 18.3 and 24.3 MPa/km at 1500m depth below surface. Variation caused by bulk rock density change of 2.48-2.07 g/cm3 from hinterland to delta front. Differential uplift of hinterland and undercompaction caused density and hence vertical stress variation)

Tingay, M.R.P., R.R. Hillis, R.E. Swarbrick & C.K. Morley (2005)- Origin and petrophysical log response of overpressures in the Baram Delta Province, Brunei. Proc. 30th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 381-390.

Tingay, M.R.P., R.R. Hillis, R.E. Swarbrick, C.K. Morley & A.R. Damit (2007)- óVertically transferredô overpressures in Brunei: evidence for a new mechanism for the formation of high-magnitude overpressure. Geology 35, 11, p. 1023-1026.
(Pore pressure data from 61 fields across Baram Delta province reveal two types of overpressure: basal pro-delta shales overpressures generated by disequilibrium compaction, overlying sand/shale deltaic sequence overpressures generated by fluid expansion. Fluid expansion overpressures in fields that were inverted during Pliocene, which resulted in large-scale fluid migration from prodelta shales into deltaic sequences)

Tingay, M.R.P., R.R. Hillis, R.E. Swarbrick, C.K. Morley & A.R. Damit (2009)- Origin of overpressure and pore-pressure prediction in the Baram Delta province, Brunei. American Assoc. Petrol. Geol. (AAPG) Bull. 93, 1, p. 51-74.
(Baram Delta overpressures in inner shelf deltaic sequences and prodelta shales, generated by disequilibrium compaction in prodelta shales and by fluid expansion in inner-shelf deltaic sequences. Overpressures in inner-shelf deltaics vertically transferred into reservoir units via faults from prodelta shales. Sediments overpressured by disequilibrium compaction different physical properties to those overpressured by vertical transfer)

Tjia, H.D. (1970)- Transcurrent faulting in the Sarawak-Kiri region, Sarawak, East Malaysia. Geol. Magazine 107, 3, p. 217-224.
(Left-lateral, NNW-SSE trending transcurrent fault in Sarawak-kiri valley, W Sarawak. Belongs to important fracture zone that extends into Kalimantan, and continues in N direction along edge of Sunda Shelf beneath S China Sea. Continental part of SE Asia rotated counter-clockwise up to Lower Paleogene)

Tongkul, F. (1999)- Regional geological correlation of Paleogene sedimentary rocks between Sabah and Sarawak, Malaysia. In: G.H. Teh (ed.) Proc. 9th Reg. Congress Geology, Mineral and Energy Resources of SE Asia (GEOSEA ô98), Kuala Lumpur 1998, Bull. Geol. Soc. Malaysia 43, p. 31-39.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1999004.pdf)
Three groups of Paleogene sedimentary rock units can be correlated regionally between Sabah and Sarawak: (1) intensely deformed, Paleocene- E Eocene turbiditic clastic sediments, partly metamorphosed to slate and metasandstone; (2) 'E Crocker' steeply dipping late Lower Eocene- early U Eocene submarine fan sandstone-shale with thrust transport directions generally to N and NW, and (3) 'W Crocker' U Eocene- U Oligocene sandstone- shale, with local conglomerate, limestone and marl, with deformation similar to Unit 2. Paleogene sediments deposited in large basin along NW Borneo. Deposition and deformation of sediments in successive stages: younger sediments were deposited on top or in front of older accreted sediments in response to NW-SE closure of elongate basin)

Tongkul, F. (2006)- The structural style of Lower Miocene sedimentary rocks, Kudat Peninsula, Malaysia. In: Petroleum Geol. Conf. & Exh. 2003, Kuala Lumpur, Bull. Geol. Soc. Malaysia 49, p. 119-124.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm2004019.pdf)

(Kudat Peninsula mostly Lower Miocene sediments, deformed into large-scale folds on three major WNW-ESE trending imbricate thrust slices. Deformation probably caused by progressive N-S transpression related to M Miocene collision of Dangerous Ground/ Reed Bank with NW Sabah along NW Borneo Trough)

Tongkul, F. (2017)- Active tectonics in Sabah- seismicity and active faults. Bull. Geol. Soc. Malaysia 64 (Geol. Soc. Malaysia 50th Anniversary Issue 2), p. 27-36.
(online at: www.gsm.org.my/products/702001-101721-PDF.pdf)
(Sabah under WNW-ESE compressive stress due W-ward movements of Philippine-Pacific plate against SE-moving Eurasian plate, causing NE-SW trending active thrust faults and NW-SE trending strike-slip faults. Resultant regional folding/ warping of upper crust produced uplifted NE-SW belt in W Sabah (Crocker-Trusmadi Range) and is thought to be driving extensional tectonics, creating 6 elongate Quaternary graben-like basins (Tenom, Keningau, Tambunan, Ranau, Timbua and Marak-Parak))

Tongkul, F. & F.K. Chang (2003)- Structural geology of the Tertiary Maliau Basin, Sabah. In: G.H. Teh (ed.) Petroleum Geology Conf. Exhib. 2002, Bull. Geol. Soc. Malaysia 47, p. 51-61.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm2003a04.pdf)
(Maliau Basin saucer-shaped basin in C and S Sabah. 7500m thick clastics section, mainly M Miocene age and deltaic- coastal facies)

Torres, J., A. Gartrell & N. Hoggmascall (2011)- Redefining a sequence stratigraphic framework for the Miocene to Present in Brunei Darussalam: roles of local tectonics, eustacy and sediment supply. Int. Petrol. Techn. Conf. (IPTC), Bangkok 2011, IPTC 15167, p. 2790-2801.
(Summary of Brunei Shell work on M Miocene- Recent deltaic sequences of Baram-Balbac Basin. Previous studies used global sequence framework and underestimated local autocyclic forcing. Revised tectono-stratigraphic framework established ten 3rd order Late Miocene- Present sequences. Some can be tied to regional compressional pulses, two sequence boundaries now calibrated to two major global eustatic falls (11.7 and 5.73 Ma). 11.7 Ma event shows ~15 km basinward shift of shelf edge, but no sub-aerial erosion on emerged shelf. The 5.73 Ma event (near Top Discoaster quinqueramus) shows modest basinward shift of shelf edge, widespread canyon incision along margin and major incision of fluvial system feeding Champion Delta)

Ujie, H. (1970)- Miocene foraminiferal faunas from the Sandakan Formation, North Borneo. In: T. Kobayasi & R. Toriyama (eds.) Geology and Palaeontology of Southeast Asia, University of Tokyo Press, 8, p. 165-185.
(Sandakan Fm on Sandakan Peninsula, NE Sabah, >4500m thick clastic series, mostly barren, 3 samples with M Miocene planktonic forams (Gr. fohsi zone))

Ujie, H. (1977)- New species and subspecies of benthonic foraminifera from the Miocene Sandakan Formation, North Borneo. In: T. Kobayasi & R. Toriyama (eds.) Geology and Palaeontology. Southeast Asia, University of Tokyo Press, 18, p. 87-102.
(Descriptions of marine benthic forams from Middle Miocene Sandakan Fm. New species of Bolivina, Ammonia, Pseudorotalia borneensis, Gyroidina, etc. No stratigraphy or biozonations)

Ulfa, Y., N. Sapari & Z.Z.T. Harith (2011)- Combined tide and storm influence on facies sedimentation of Miocene Miri Formation, Sarawak.Eksplorium 32, 2, p. 77-89.
(online at: jurnal.batan.go.id/index.php/eksplorium/article/download/2814/2586)

Vachard, D. (1990)- A new biozonation of the limestones from Terbat area, Sarawak, Malaysia. In: H. Fontaine (ed.) Ten years of CCOP research on the Pre-Tertiary of East Asia, CCOP Techn. Publ. 20, p. 183-208.
(Terbat Lst of W Sarawak- NW Kalimantan border area with 7 diverse M Carboniferous- earliest Permian fusulinid assemblages: M Carboniferous with (1) Profusulinella- Goksuella and (2) Beedeina- Komia; (3) latest Carboniferous with (3) Dutkevichites and (4) Pseudofusulina-Ozawainella; (5) earliest Permian (lower Asselian) with Occidentoschwagerina fusulinoides, Ozawainella (=Nummulostegina velebitana of Cummings); (6) M-U Asselian with Ozawaiella angulata, Schwagerina, Boultonia willsi, Tricitites and (7) U Artinskian with Langella ex. gr. perforata (= Padangia perforata Lange 1925) and common Permocalculus. Sarawak assemblages most similar to S and N China and Alps)

Vahrenkamp, V.C. (1998)- Miocene carbonates of the Luconian Province, Offshore Sarawak: implications for regional geology and reservoir properties from Strontium-isotope stratigraphy. In: G.H. Teh (ed.) Geol. Soc. Malaysia Petrol. Geol. Conf., Kuala Lumpur 1997, Bull. Geol. Soc. Malaysia 42, p. 1-13.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1998001.pdf)
(Luconia province E-M Miocene carbonate platforms growth and demise correlated with 2nd-order eustatic sea-level cycle. Sr isotopes suggest late E Miocene- Middle/Late Miocene boundary ages. Major karst horizons, flooding, aggradation and progradation packages linked to 3rd order eustatic sea-level fluctuations. Simultaneous with 2nd order sea-level drop (late M Miocene) influx of siliciclastics split province into S part with low relief carbonate banks and N part with high relief platforms. All growth terminated at end M Miocene. Low relief banks buried, high relief platforms karstified prior to drowning (Late Miocene-Pliocene). Porosity-permeability distribution linked to duration of exposure and burial diagenesis)

Vahrenkamp, V.C., F. David, P. Duijndam, M. Newall & P. Crevello (2004)- Growth architecture, faulting, and karstification of a Middle Miocene carbonate platform, Luconia Province, Offshore Sarawak, Malaysia. In: G.P. Eberli et al. (eds.) Seismic imaging of carbonate reservoirs and systems, American Assoc. Petrol. Geol. (AAPG), Mem. 81, p. 329-350.
(Mega Platform is 30x50-km large and 1.2-km-thick carbonate platform, originating in late Early- early M Miocene on structural high. First aggraded, then backstepped in M Miocene. Several transgressive, aggradational, and progradational cycles overprinted by karst events. Demise of platform either drowning from combined subsidence- eustatic sea level rise, or much-later drowning, preceded by period of exposure resulting from second-order sea level fall and decrease in subsidence caused by onset of Late Miocene tectonism in Borneo. Hiatus of ~5 m.y. before platform was buried by deep-marine siliciclastics prograding from large NW Borneo deltas. Growth architecture, faulting and karstification key to exploiting hydrocarbon reservoirs)

Vahrenkamp, V.C., Y. Kamari & S.A. Rahman (1998)- Three dimensional reservoir geological model and multiple scenario volumetrics of the F23 Miocene carbonate build-up, Luconia Province, offshore Sarawak. Bull. Geol. Soc. Malaysia 42, p. 15-26.
(online at: www.gsm.org.my/products/702001-100860-PDF.pdf)
(Gas reservoirs in M Miocene carbonate builups of C Luconia with complex internal reservoir architecture influenced by paleo-wind pattern and sea level fluctuations, with backstepping, progradational and aggradational growth phases. Transgressive systems dense argillaceous limestones, possibly isolating gas volumes. During repeated periods of flooding platform backstepped up-wind, then prograded down-wind again during sea level high stands. Most likely gas volume in F23 field 3.98 Tcf)

Van Borren, L.K., A. Koopman & A.J. Schreurs (1996)- Stratigraphy. In: S.T.Sandal (ed.) The geology and hydrocarbon resources of Negara Brunei Darussalam (2nd ed.), Spec. Publ. Muzium Brunei and Brunei Shell Petroleum Company Berhad, Syabas, Bandar Seri Begawan, p. 81-128.
(Includes review of biostratigraphy in Brunei region (p. 81-96))

Van den Brink, H. (2001)- Neogene dinoflagellate cysts from a deep water well, offshore Sabah, northern Borneo. Berita Sedimentologi 16, p. 22-25.
(Study of marine dinoflagellate cysts in U Miocene- Pliocene of deep water well offshore Sabah. Potential useful 'tops' in Pliocene: Hystrichokolpoma rigaudiae, H. okinawinum, Dapsilidinium pastielsi, Lingulodinium pycnospinosum. For U Miocene: Selenopemphix brevispinosa and Systematophora placacantha)

Van den Brink, H. (2002)- Neogene dinoflagellate cysts from a deep water well, offshore Sabah, northern Borneo. Proc. 34th Ann. Mtg. American Assoc. Stratigr. Palynologists (AASP), p. 278-279. *(Abstract only)*
(Attempt to establish dinoflagellate cyst biozonation for Late Miocene- Recent in deep-water wells off Sabah and Brunei. Palynological assemblages dominated by land plant material; marine elements (dinoflagellate cysts, acritarchs, algae) only 2-5% of microflora. Dinoflagellate cyst assemblages similar to open oceanic assemblages from E Indian Ocean and NE Australian margin)

Van den Brink, H. (2019)- The stratigraphic distribution of Neogene dinoflagellate cysts from a deep water well, Offshore Sabah, Northern Borneo. Berita Sedimentologi 43, p. 15-28.
(online at: https://www.iagi.or.id/fosi/files/2019/06/FOSI_BeritaSedimentologi_43_June_2019.pdf)
(Late Miocene- Pliocene dinoflagellate cyst distribution in well Kebabangan-1, deep water offshore Sabah. Dinoflagellate cysts recovered from mud-rich shelfal topsets and underlying mud-rich slope fan systems, while basal sand-rich base-of-slope fans barren of palynomorphs)

Van der Zee, W. & J.L. Urai (2005)- Processes of normal fault evolution in a siliciclastic sequence: a case study from Miri, Sarawak, Malaysia. J. Structural Geol. 27, 12, p. 2281-2300.

Van Hattum, M., R. Hall & G.J. Nichols (2003)- Provenance of northern Borneo sediments. Proc. 29th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, p. 305-319.
(Upper Cretaceous- Eocene sediments mature quartzose, possibly derived from mainland SE Asia/Indochina. In Eocene shift to relatively immature recycled orogenic sands. Eo- Oligocene Crocker Fm mainly derived from granites; ultimate source probably S Borneo Schwaner Mountains)

Van Hattum, M.W.A., R. Hall, A.L. Pickard & G.J. Nichols (2006)- Southeast Asian sediments not from Asia: provenance and geochronology of North Borneo sandstones. Geology 34, 7, p. 589-592.
(Eocene- Lower Miocene Crocker turbidite sst of N Borneo derived from Borneo and SE Asia, not from Asian sources after India-Eurasia collision. Compositionally mature due to tropical weathering, but mostly first-cycle sandstones from granitic and subordinate metamorphic, sedimentary and ophiolitic rocks. Detrital zircons Archean- Eocene ages, mostly Mesozoic. Main source Cretaceous granites of Schwaner Mts in SW Borneo in Eocene, Permo-Triassic granites and Proterozoic basement of Malay-Thai Tin Belt in Oligocene)

Van Hattum, M.W.A., R. Hall, A.L. Pickard & G.J. Nichols (2013)- Provenance and geochronology of Cenozoic sandstones of northern Borneo. J. Asian Earth Sci. 76, p. 266-282.
(Crocker Fan of Sabah deposited during subduction of Proto-South China Sea in Eocene- E Miocene. Collision of microcontinental blocks with N Borneo in E Miocene terminated deep water sedimentation and resulted in regional Top Crocker Unconformity, followed by sedimentation of fluvio-deltaic- shallow marine facies in late E Miocene. Crocker Fan sandstones derived from sources in Borneo and nearby SE Asia. Sandstones mostly from granitic sources, with some metamorphic, sedimentary and ophiolitic material. In Eocene sands mainly Cretaceous zircons (~90-130 Ma; from granites of Schwaner Mts). In Oligocene sands more common zircons from Permian-Triassic granites (~213-268 Ma) and Paleoproterozoic (~1850 Ma) from basement of Malay Tin Belt. Miocene fluvio-deltaics mostly recycled from deformed Crocker Fan. Lower Miocene Tajau Sst of Kudat

Fm in N Sabah derived mainly from granitic and high-grade metamorphic source rock, probably from N, from continental crust from S China and subduction-related metamorphic rocks)

Van Heck, S.E. (2001)- Calcareous nannoplankton and planktonic foraminifera from the Neogene offshore Northwest Borneo. Berita Sedimentologi 16, p. 14-21.

Wilford, G.E. & C.H. Kho (1965)- The geology and mineral resources of the Penrissen area, West Sarawak, Malaysia. Malaysia Geol. Survey Borneo Region, Rept. 2, p. 1-195.
(Description of geology and 1:50,000 scale geologic map of area S of Kuching along NW Kalimantan border. Named after 4350' high Penrissen Peak, which is on border, composed of Plateau Sandstone. Oldest rock U Triassic Sadong Fm (with U Triassic bivalves Halobia, Grammatodon, Monotis salinaria, etc.) and Serian Volcanics. Triassic unconformably overlain by Kedadom Fm with Kimmeridgian ammonoids Lithacoceras and Subplanites sp. Conformably overlain by Bau Lst with latest Jurassic- E Cretaceous algae (Cladocoropsis, Clypeina, Salpingoporella, Thaumatoporella, etc.) and foraminifera (Pseudocyclammina lituus, Nautiloculina oolithica). Widespread Cretaceous Pedawan Fm with radiolaria, Etc..)

William, A.G., J.J. Lambiase, S. Back & M.K. Jamiran (2003)- Sedimentology of the Jalan Selaiman and Bukit Melinsung outcrops, western Sabah: is the West Crocker Formation an analogue for Neogene turbidites offshore? In: G.H. Teh (ed.) Petroleum Geology Conf. Exhib. 2002, Bull. Geol. Soc. Malaysia 47, p. 63-75.
(online at: www.gsm.org.my/products/702001-100608-PDF.pdf)
(Outcrop study of~500m of Oligocene- E Miocene West Crocker Fm turbidites, W Sabah. Texturally immature sands. Paleocurrent directions consistently to N, oblique to NE-SW marginal basin, possibly derived from uplifted Rajang accretionary prism)

Wilson, M.E.J., E. Chang Ee Wah, S. Dorobek & P. Lunt (2013)- Onshore to offshore trends in carbonate sequence development, diagenesis and reservoir quality across a land-attached shelf in SE Asia. Marine Petroleum Geol. 45, p. 349-376.
(online at: http://searg.rhul.ac.uk/pubs/wilson_etal_2013%20Offshore%20Borneo%20carbonate%20trends.pdf)
(Onshore to offshore trends in carbonate development and reservoir quality assessed across Late Oligocene-Miocene of NW Borneo (Sarawak) shelf from outcrops and wells. Carbonates developed as localised build-ups and more continuous sheet-like deposits in near-coast to shelf margin positions. Most samples show evidence for marine micritisation and in shelf margin positions isopachous cements. Burial diagenesis predominates (compaction, neomorphism, fracturing, late leaching, dolomitisation). Some early, probable meteoric leaching affected inner shelf deposits prior to pervasive calcite cement formation, probably reflecting alteration from terrestrial groundwaters in meteoric aquifers derived from humid landmass of Borneo. Best porosity (20-35%) in outer shelf- shelf margin high energy grainstones and rudstones that experienced minimal clastic influx, most commonly from backstepping to aggradational carbonate sequences)

Wilson, R.A.M. (1961)- The geology and mineral resources of the Banggi island and Sugut River area, North Borneo. Geol. Survey Dept., British Territories in Borneo, Memoir 15, p. 1-143.
(Geology of NE Borneo Banggi and Balamban Islands off N tip of Sabah and mainland Sugut river area. Thick Late Eocene-Miocene Crocker Fm geosynclinal sequence on mainland, mainly S/ SW dipping. On islands imbricated, sheared (strike N, shearing towards W), Chert-Spilite Fm of Upper Cretaceous or Lower Eocene pillow lavas, basaltic intrusions and chert beds, brecciated and intruded by serpentinite sheets and younger ultrabasic plutonics. S Banggi Fm with E Miocene (Te5) limestones, some with reworked Eocene Discocyclina and ?Pellatispira). M Miocene (lower Tf) Balambangan Lst with Miogypsina, Katacycloclypeus annulatus)

Wilson, R.A.M. (1963)- The Chert-Spilite Formation of North Borneo. In: F.H. Fitch (ed.) Proc. British Borneo Geological Conference 1961, Kuching, Bull. Geol. Survey Dept., British Territories in Borneo, 4, Kuching, p. 61-78.

('Chert-spilite Fm sediments form NE/NNE trending discontinuous 'ophiolitic' belt across C-E Sabah, from Sempurna Peninsula in SE to Kota Belud in NW and Balambangan- Banggi Islands in N. Mainly deep marine radiolarian cherts, basaltic volcanics (pillow lavas), graywacke sandstones and serpentinite sheets of Cretaceous- Eocene age. All strongly imbricated and often look like slickensided breccias. Also breccias with boulders in clay matrix. Relationships with underlying and overlying formations not clear. Most of tectonic activity predates Crocker and Kulapis Fm)

Wilson, R.A.M. (1964)- The geology and mineral resources of the Labuan and Padas Valley area, Sabah, Malaysia. Geol. Survey Borneo Region, Malaysia, Memoir 17, p. 1-150.

Wolfenden, E.B. (1960)- The geology and mineral resources of the lower Rajang Valley and adjoining areas, Sarawak. Geol. Survey Dept., British Territories in Borneo, Memoir 11, p. 1-167.
(Area of C Sarawak with mainly Upper Cretaceous- Recent sediments and rare Tertiary intrusive and extrusive igneous rocks. Thick Upper Cretaceous- Upper Eocene deep water Rajang Fm series of mildly dynamically metamorphosed argillaceous rocks, sandstone, and conglomerate, intensely folded in Late Eocene. Oldest rocks Upper Cretaceous (with Globotrunca, Orbitolina)- U Eocene Belaga Fm (incl. Pellatispira, Discocyclina, planktonics). Tatau Fm with rich Eocene- Oligocene foraminifera. In NE thick Upper Eocene- Pliocene sandstones and shales with thin Late Eocene limestones and volcanics. Upper Eocene- Pliocene rocks folded)

Wolfenden, E.B. (1961)- Molluscs from the Bau Formation of the Tebakang area, First Division. Annual Report Geological Survey Dept., British Territories in Borneo, 1960, Kuching, p. 47-
(Brief note on Late Jurassic fauna in conglomeratic shale of Bau Lst Fm of W Sarawak: ammonites (Lithacoceras or Subplanites), bivalves (Nuculana, Cucullaea, Astare, Corbula). No figures)

Wolfenden, E.B. (1961)- Bauxite in Sarawak. Economic Geology 56, 5, p. 972-981.
(Tropical weathering of basic and intermediate igneous rocks generated bauxite (= >40% alumina) deposits of W Sarawak, W of Lupar River. Highest-grade material (Munggu Belian) formed from pyroxene andesite; other parent materials gabbro, diorite, plagioclase amphibolite and altered andesites and basalts. Bauxite consists mainly of gibbsite. In Sarawak local local company Sematan Bauxite Ltd started mining bauxite in 1957 at Munggu Belian and Bukit Gebong near, Sematan)

Wolfenden, E.B. (1963)- Sematan and Lundu area, West Sarawak. British Borneo Geol. Survey Report 1, p. 1-159.
(Includes detailed descriptions of bauxite occurrences)

Wolfenden, E.B. (1963)- Bauxite in West Sarawak. In: F.H. Fitch (ed.) Proc. British Borneo Geological Conference 1961, Kuching, Bull. Geol. Survey Dept., British Territories in Borneo, 4, p. 119-136.
(Bauxite deposits (= rocks with >40% alumina) in W Sarawak only W of Lupar River (rel. old 'Continental core' of Borneo). Possibly commercial deposits near Sematan. Formed from tropical weathering of intermediate-basic igneous rocks (andesite, gabbro and altered dolerite))

Wolfenden, E.B. (1965)- Geochemical behaviour of trace elements during bauxite formation in Sarawak, Malaysia. Geochimica Cosmochimica Acta 29, 9, p. 1051-1062.
(Bauxite and kaolinitic clay formed by weathering of andesite lava under humid tropical conditions in W Sarawak. At Sematan bauxite is ~10' thick on hills and extends under surrounding alluvial sand and clay where composition secondarily modified (swamp bauxite). During formation of hill bauxite, Cr, Zr and Ga are concentrated, Ni, Co, P, Mn, Sr and Y are depleted. No geology details)

Wolfenden, E.B. (1965)- Bau mining district, West Sarawak, Malaysia, Part 1: Bau. Geol. Survey Borneo Region, Malaysia, Bull. 7, 1, p. 1-147.
(Geologic map of part of W Sarawak, SW of Kuching, an area with long history of gold-siver mining. Includes description of >1800' thick, massive Upper Jurassic Bau Limestone with foram Pseudocyclammina lituus, algae Thaumatoporella parvovesiculifera, stromatoporoid Cladocoropsis mirabilis and also Calpionella. Locally with sandstone- pebbly sandstones with abundant igneous rock fragments at base, unconformable on U Triassic

basaltic Serian volcanics. Conformably overlain by >10,000' of marine Cretaceous Pedawan Fm, now mostly eroded in Bau region. Upper Cretaceous folding phase, strongest NW of Bau, rel. minor to SE, followed by deposition of Plateau Sandstone. Also probably M Miocene folding phase. Acidic igneous intrusions of probably M Miocene age.)

Wolfenden, E.B. & N.S. Haile (1963)- Sematan and Lundu Area, West Sarawak. Explanation of sheets 1-109-3, 1-109-4, 1-109-7, 1-109-8 and 2-109-15. Geol. Survey Dept., British Territories in Borneo, Kuching, Report 1, p. 1-159.
(Geologic maps at 1:50,000 scale of W-most part of Sarawak, W of Kuching, bordering W Kalimantan. Oldest rocks thick, intensely folded and locally metamorphosed Jurassic- Cretaceous Serabang Fm flysch, radiolarian chert and ultrabasics (mainly gabbro-dolerite). Interpreted as 'geosynclinal' series (Hamilton 1979 and Hutchison 2005 suggest this is Lower Cretaceous melange, similar to Lubuk Antu/ 'Lupar Line' further East; it is accretionary prism formed during Early Cretaceous subduction of Proto China Sea from N. Unconformably overlain by gently-dipping Paleogene? Plateau Sandstone)

Wolfenden, E.B. & H.J.C. Kirk (1967)- Bauxite and laterite in British Territories in Borneo. The Philippine Geologist (J. Geol. Soc. Philippines) 21, 3, p. 102-116.
(Bauxite was found at Sematan in W Sarawak in 1949. Further prospecting in Sarawak and N Borneo from 1950-1952 not successful. In Sarawak some laterite associated with bauxite, but not economic. Bauxite and laterite present in N Borneo, but extent little known)

Wong, R.H.F. (1993)- Sequence stratigraphy of the Middle Miocene-Pliocene Southern offshore Sandakan Basin, East Sabah. In: G.H. Teh (ed.) Proc. Symposium on the Tectonic framework and energy resources of the western margin of the Pacific Basin, Kuala Lumpur 1992, Bull. Geol. Soc. Malaysia 33, p. 129-142.
(Offshore Sandakan Basin sequence stratigraphic study based on seismic and 8 wells. Three main units: (1) M Miocene- early U Miocene (moderate progradation; five 3rd order sequences); (2) middle U Miocene (high progradation, low aggradation; three 3rd order sequences); (3) late U Miocene- Pliocene (high aggradation, low progradation; five 3rd order sequences. Shelf edges mainly N-S trending and prograding East)

Wong, R. (1996)- Seismic sequence stratigraphic interpretation enhances remaining hydrocarbon potential of the SE Collins Field. In: G.H. Teh (ed.) Petroleum Geology Conf. 1995, Bull. Geol. Soc. Malaysia 39, p. 223-240.
(online at: www.gsm.org.my/products/702001-100895-PDF.pdf)
(SE Collins field 1972 marginal oil field discovery in complexly faulted central portion of the Inboard Belt of NW Sabah Basin. Elongated, N-S anticlinal structure with reverse faults on N, W and S. Main reservoirs M Miocene sands. New sequence stratigraphic study lead to doubling of reserves estimate)

Wong, R.H.F. (1997)- Sequence stratigraphy of the Upper Miocene Stage IVC in the Labuan-Paisley Syncline, NW Sabah Basin. Bull. Geol. Soc. Malaysia 41, p. 53-60.

(Lingan fan system on steep (2-4°) NW Borneo margin off Sabah, located in a toe-thrust foldbelt area in front of E Baram Delta. With mass transport complexes in channelised fan systems

Zampetti, V. (2004)- Interdependence of seismic imaging and sedimentology (Miocene carbonate platforms, South China Sea). Doct. Thesis Vrije Universiteit, Amsterdam, p. 1-134. *(Unpublished)*

Zampetti, V. (2010)- Controlling factors of a Miocene carbonate platform: implications for platform architecture and off-platform reservoirs (Luconia Province, Malaysia). In: W.A. Morgan, A.D. George et al. (eds.) Cenozoic carbonate systems of Australasia, Soc. Sedimentary Geology (SEPM), Spec. Publ. 95, p. 129-145.
(Growth of Luconia Province carbonate platform began in Late Oligocene- Early Miocene by coalescence of isolated patch reefs, and includes phases of progradation, backstepping and occasional collapse of platform flanks, terminated by gradual drowning. Platform margins asymmetry related to ocean currents rather than wind. Platform affected by strike-slip deformation during sedimentation. Platform material also deposited as slide masses in adjacent basin floor, passing into debris-flow and turbidites and can extend many km's across basin floor. Much secondary porosity dissolution during deep burial)

Zampetti, V., W. Schlager, J.H. van Konijnenburg & A.J. Everts (2003)- Depositional history and origin of porosity in a Miocene carbonate platform of Central Luconia, offshore Sarawak. In: G.H. Teh (ed.) Petroleum Geology Conf. Exhib. 2002, Bull. Geol. Soc. Malaysia 47, p. 139-152.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm2003a10.pdf)
(Seismic and core study of unidentified M-Late Miocene carbonate platform in Luconia province. Buildup growth primarily vertical aggradtion, with flat top, with backstepping of margin. Two phases of progradation, youngest steep and with segments of slope collapsing in large landslides. Porosity very heterogeneous, mostly secondary and related to dissolution under deep burial conditions)

Zampetti, V., W. Schlager, J.H. van Konijnenburg & A.J. Everts (2004)- Architecture and growth history of a Miocene carbonate platform from 3D seismic reflection data; Luconia province, offshore Sarawak, Malaysia. Marine Petroleum Geol. 21, 5, p. 517-534.
(online at: http://www.personal.kent.edu/~jortiz/carbonates/seismic1.pdf)
(Luconia carbonate platform growth started in Late Oligocene-E Miocene by coalescence of isolated patch reefs. Growth history includes phases of progradation, backstepping and collapse of platform flanks. Most pronounced seismic reflections correspond to flooding events. Subaerial exposure demonstrated in only one case. Platform growth terminated by gradual drowningin Late Miocene)

Zampetti, V., W. Schlager, J.H. van Konijnenburg & A.J. Everts (2004)- 3-D Seismic characterization of submarine landslides on a Miocene carbonate platform (Luconia Province, Malaysia). J. Sedimentary Res. 74, 6, p. 817-830.
(Submarine landslides on flanks of Miocene carbonate platform. Chaotic deposits basinward of slide scar widen in transport direction and end in indistinct lobes. Slide masses extend for 1.5 km into basin, with130m maximum thickness. Slide deposit on W flank two events, separated by smooth reflection interpreted as hemipelagic mud between carbonate-rich slide masses. Syndepositional faulting affects geometry of platform margins, particularly at time of slope failure)

Zheng, Q.L., S.Z. Li, Y.H. Suo, X.Y. Li, L.L. Guo, P.C. Wang, Y. Zhang, Y.B. Zang, S.H. Jiang & I.D. Somerville (2016)- Structures around the Tinjar-West Baram Line in northern Kalimantan and seafloor spreading in the Proto South China Sea. Geological J. 51, Suppl. S1, p. 513-523.
(Tinjar-West Baram Line is NW-trending trans-lithospheric fault in N Borneo; its NW extension into S China Sea is W Baram Line. Originated as NE/NNE-trending transform fault during spreading of Proto-South China Sea before 35 Ma and before NW trending strike-slip movement since Oligocene)

Zielinski, G.W., M. Bjoroy, R.L.B. Zielinski & I.L. Ferriday (2007)- Heat flow and surface hydrocarbons on the Brunei continental margin. American Assoc. Petrol. Geol. (AAPG) Bull. 91, 7, p. 1053-1080.
(Brunei margin thermogenic hydrocarbons in landward half of study area (heat flow 83.7 ± 66.5 mW/m2). Seaward, mean heat flow is 59.0 ± 22.6 mW/m2, and surface thermogenic hydrocarbons largely absent. Low-heat-flow zone coincides with Palawan Trough paleosubduction zone. High-heat-flow zone of seepage coincides with land-derived Baram delta sediments, constituting a pseudo-accretionary prism)

IV.4. Makassar Straits

Aini, S.N., R. Hall & C.F. Elders (2005)- Basement architecture and sedimentary fill of the North Makassar Basin. Proc. 30th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, p. 483-497.
(N Makassar Basin probably underlain by extended continental crust rather than oceanic crust. Age of rifting M-L Eocene. Mainly thin, deepwater sediment. Becomes foreland basin in E Pliocene with W-ward propagation of W Sulawesi fold-thrust belt, resulting in increase in sediment supply from E)

Argakoesoemah, R.M.I. (2017)- Middle Eocene palaeogeography of the greater Makassar Straits region, Indonesia: a review of Eocene source rock distribution. Proc. 41st Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA17-247-G, 22p.
(Review of E-M Eocene synrift sediments of Makassar Straits wells and proto-Barito and Kutai and W Sulawesi basins, areas with similar Eocene stratigraphies. Non-marine syn-rift deposition likely initiated M Eocene, in peripheral foreland basin, with widespread marine shales by Late Eocene. Area of well-developed lacustrine M Eocene in E part of S Makassar Basin)

Argakoesoemah, R.M.I., H.B. Nainggolan, I. Wahyudi, A. Hidayat & M.F. Shahab (2016)- Fluvial-to-deepwater stratigraphy and structural development of southern part of North Makassar Basin, Indonesia. Proc. 40th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA16-728-G, 23p.
(Review of Eocene- Recent stratigraphy of S part of N Makassar Basin. E Eocene non-marine synrift sequences overlain by Late Eocene late rift and Oligocene-younger post rift deepwater deposits across basin, exception for Paternoster Platform area. Late Early Eocene (~47 Ma) seafloor spreading initiated in Celebes Sea and was believed to extend to SW into N Makassar Basin, but still controversial. Major inversion-uplift of Paternoster Platform in M Miocene)

Ariyono, D., J. Kupecz, I. Sayers, C. Tanos & A. Hilman (2013)- Source rock and thermal calibration for timing of generation and expulsion in the South Makassar Basin, Indonesia. Proc. 37th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA13-G-160, p. 1-20.
(Hydrocarbons in wells in S Makassar Basin area (Ruby Field gas, Pangkat-1 oil, Sultan-1 gas) confirm presence of working petroleum system. Geochemical analyses from Kelara-1, Makassar Straits-1, Martaban-1 and Pangkat-1 suggest main source in M Eocene coals and lacustrine shales. Late Eocene little or no source potential. Hydrocarbon generation started at ~20 Ma in S Makassar Basin and 12 Ma in Pangkat Graben. Timing of hydrocarbon generation relative to seal emplacement is critical risk for pinnacle reefs like Sultan-1)

Armandita, C. (2014)- The geometry and origin of gravity-controlled structures: mass transport complex (giant slump) in South Makassar Strait basin. Proc. 43rd Ann. Conv. Indon. Assoc. Geol. (IAGI), Jakarta, PIT IAGI 2014-048, 6p.
(Large, but rel. coherent Pliocene Mass Transport Complex (deep water gravity slump) identified in S Makassar Strait Basin, with area >9000 km2 and volume of 2438 km3. Derived from NW)

Armandita, C., C.K. Morley & P. Rowell (2015)- Origin, structural geometry, and development of a giant coherent slide: The South Makassar Strait mass transport complex. Geosphere 11, 2, p. 376-403.
(S Makassar Strait Mass Transport Complex with extensional headwall region in upper slope of Paternoster Platform. Area of >9000 km2, volume 2438 km3, core region thickness ~1.7km. Composed of shale-dominated sediments. With relatively coherent internal stratigraphy. Toe region deformed into thrust-related structures. Probably caused by caused by ~2° seaward rotation of Paternoster platform in Pliocene. ~6-7 km of shortening in toe region of MTC occurred at slow strain rate)

Azidin, N.F.N., A. Balaguru & N. Ahmad (2011)- Structural styles of the North West Sabah and West Sulawesi fold thrust belt regions and its implication to the petroleum system- a comparison. In: Petroleum Geology Conference and Exhibition 2011, Kuala Lumpur, Poster 23, p. 173-176. *(Extended Abstract)*

(online at: http://jgsm.geologi.esdm.go.id/index.php/JGSM/article/view/113/105)
('Compressional phase in Makassar Straits based on geological land data, marine seismic and satellite imagery'. Last deformation phase in Makassar Strait is compressional, unlike older extensional phase that formed Makassar Strait. Seismic data from E part of Makassar Strait and outcrop geology in W Sulawesi show W-verging fold-thrust system that is still active today. Thrust-fold structures in onshore E Kalimantan and offshore W Makassar Straits show vergence to E)

Baillie, P. & J. Decker (2011)- The Makassar Straits new thoughts on an old area. Proc. 2011 SE Asia Petroleum Expl. Soc. (SEAPEX) Conference, Singapore, 35p. *(Abstract + Presentation)*
(Makassar Straits formed by M Eocene extension, typical Sundaland, grabens and half-grabens. With top syn-rift unconformity of Late Eocene (38-40 Ma) age. Basement is stretched continental crust. Deepwater sediments deposited in response to tectonic events in adjacent Borneo and Sulawesi in Late Eocene- Neogene. M Miocene pulse of E-directed quartzose turbidites deposited in deepwater. All petroleum system elements present)

Baillie, P. & J. Decker (2012)- Geological development of the Straits of Makassar, Indonesia. AAPG Int. Conv. Exhib., Singapore 2012, Search and Discovery Art. 30251, p. 1-4. *(Extended Abstract)*
(online at: www.searchanddiscovery.com/documents/2012/30251baillie/ndx_baillie.pdf)
(Makassar Straits resulted from M Eocene (42 Ma) extension, creating grabens and half-grabens in continental or marginal marine setting. In central part of Strait up to 4km of deep marine sediment above Late Eocene (~36 Ma) top syn-rift unconformity. Turbidite sediments both W- and E-directed (major Borneo-derived pulse in E-M Miocene; sediments from Sulawesi in latest Miocene-Pliocene. While classic turbidite sedimentation has occurred, hyperpycnal flow from tropical river floods contributed substantially to fill of Makassar Strait)

Baillie, P., P. Gilleran, W. Clark, S.J. Moss, A. Stein, E. Hermantoro & S. Oemar (1999)- New insights into the geological development of the deepwater Mahakam delta and Makassar Straits. Proc. 27th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta 1999, p. 397-402.
(New non-exclusive 2D seismic survey revealed new insights into geological evolution and prospectivity of N Makassar Straits. Neogene deepwater basin floor fans and channel complexes identified in Neogene. Near present-day shelf edge of Mahakam Delta area discontinuous NNE-trending, E-verging imbricate fold-thrust system, with folding age younging to E. M Eocene-Oligocene shales acted as regional decollement. Thrusts primarily gravitational deformation of delta toe and can often be linked to extensional slope graben and regional growth faults updip)

(eds.) 3D seismic technology: application to the exploration of sedimentary basins. Geol. Soc., London, Mem. 29, p. 25-33.
(Seismic examples of slope channes and basin floor fans. Large depocentres occur where gradients are low and system switches from confined to unconfined. Erosionally confined channels feed basin floor fans at toe-of-slope, while channels confined by levees feed fans on 'distal' basin floor)

Fraser, T.H. & L.A. Ichram (1999)- Significance of Celebes Sea spreading centre to the Paleogene petroleum systems of the SE Sunda Margin, Central Indonesia. Proc. 27th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, p. 431-441.
(Celebes Sea is Eocene spreading centre active until ~37 Ma, same time as Sarawak Orogeny. About 300 km of Paleogene Celebes oceanic crust now partly consumed by Minahasa Trench. Makassar Straits is continuation of Celebes Sea extension. Paleogene clastics much thicker in SW Sulawesi than in Barito Basin. Source of clastics in Sangkarang Graben proposed to be craton of west C Kalimantan. Development of S Makassar Straits ruptured proto-Barito fluvial system which previously flowed from Kalimantan into Flores Sea)

Fraser, T.H., B.A. Jackson, P.M. Barber, P. Baillie & K. Myers (2003)- The West Sulawesi foldbelt and other new plays within the North Makassar Straits- a prospectivity review. Proc. 29th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, G-171, p. 429-450.
(Makassar Straits started in Eocene in response to extension propagating SW from Celebes Sea spreading centre. After initial opening of Straits, Eocene horst- graben terrains overlain by Oligocene-Miocene basinal sag sediments. Following Neogene uplift of Borneo and outbuilding of Mahakam Delta, considerable amounts of sediment redeposited as turbidite facies in N Makassar Basin. Plio-Pleistocene inversion of extensional areas as successive micro-continental fragments from Australian Plate collided with SE margin of Sundaland. This collision assembled Sulawesi into K-shape and formed W Sulawesi Fold Belt, which obscures E part of original Makassar Straits Eocene rift. Traps in foldbelt compressional folds over thin-skinned detachment in probably overpressured Late Eocene- E Miocene mudrocks. Neogene turbidite reservoirs postulated charged from Paleogene and Neogene source rocks)

Jackson, B.A. (2004)- Seismic evidence for gas hydrates in the North Makassar basin, Indonesia. Petroleum Geoscience 10, p. 227-238.
(Gas hydrates suggested by bottom simulating reflectors (BSR), primarily in offshore extension of W Sulawesi Fold Belt. Turbidites in fold belt mini-basins provide reservoir and source of organic material for production of biogenic methane gas. Geothermal gradients from BSR database av 4.7°C/100m)

Jackson, B.A. (2004)- Gas hydrates in the North Makassar Basin, Indonesia. In: R.A. Noble et al. (eds.) Deepwater and Frontier Exploration in Asia Symposium, Indon. Petroleum Assoc. (IPA), Jakarta, p. 373-375.
(Gas hydrate in deep-water N Makassar Straits. Sediments in West Sulawesi Fold Belt sourced from Mahakam Delta until Late Pliocene, when tectonic event in Sulawesi reversed direction of sediment transport. Sulawesi fold-belt numerous thrust sheets, creating long anticlinal structures and intervening mini-basins. Most BSR anomalies concentrated on E side of study area in vicinity of WSFB ~300 ms below seafloor. No figures)

Johansen, K., S. Maingarm & A. Pichard (2007)- Hydrocarbon potential of the South Makassar Basin, Indonesia. Proc. SE Asia Petroleum Expl. Soc. (SEAPEX) Conf. 2007, Singapore, 43p. *(Abstract + Presentation)*
(S Makassar Basin unexplored area in 1000-2000m water. Sulawesi Fold Belt to E, Paternoster Platform to W and E Java Sea/Doang Platform to S. Separated from N Makassar Basin by Adang strike slip Fault Zone. S Makassar rift basins part of Eocene extensional phase from C Java to onshore S Sulawesi. Half graben syn-rift fill two seismic facies: lower main rift non marine clastics, upper sequence late syn-rift or early post rift marine clastics. Syn-rift fill >2 km thick and potential source rock. DHI's and gas anomalies indicate active petroleum system. Structural plays mainly defined by Eocene rift phase. Main reservoirs Oligocene carbonates and Eocene- E Oligocene clastics over basement highs. Platform carbonates and pinnacle type reefs may have better reservoirs. Oligocene-E Miocene turbidities possible secondary play. Post-rift thermal subsidence resulted in 3-4 km of mudstone- shales. Late Miocene-Pliocene compressional tectonics resulted in minor deformation of S Makassar Basin, resulting in N-S trending folds and thrusts along Sulawesi Fold Belt)

Kacewicz, M., J. Decker, R. Lin, C. Stuart, P. Taylor & E. Johnson (2002)- A new regional heat flow and hydrocarbon migration model for the Kutei Basin and Central Makassar Straits. AAPG Ann. Mtg., Houston, Texas *(Abstract)*.
(New heat flow model based on crustal stretching in deepwater Kutei basin and C Makassar Straits. Heat flow varies from 32-44mW/m2 in shallow water to 45- 52 mW/m2 in deepwater at present. No significant difference between deepwater heat flow N and S of Mahakam delta and no basinward cooling)

Kapid, R., K.T. Dewi & A. Muller (2004)- New biostratigraphic sub-biozonation for Indonesia, derived from calcareous nannoplankton and ostracode assemblage in Makassar Strait. 5th Int. Conf. Asean Marine Geology, Bangkok 2004, p.

(S Makassar Basin is rift basin initiated in Eocene, subsequently inverted since E Miocene (incl. M Miocene uplift/ inversion in Paternoster High. Three exploration wells found mainly gas, suggesting S Makassar Basin essentially gas prone, but 3D thermal model suggest significant oil rim may exist in periphery of basin)

Ruzuar, A.P., R. Schneider, A.H. Saller & J.T. Noah (2005)- Linked lowstand delta to basin-floor fan deposition, Offshore East Kalimantan: an analogue for deepwater reservoir systems. Proc. 30th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 467-482.

Saller, A. (2013)- Pleistocene shelf-to-basin depositional systems, offshore East Kalimantan, Indonesia: insights into deep-water slope channels and fans. AAPG Distinguished Lecture, 2012-2013 Lecture Series, Search and Discovery Art. 50847, 52p. *(Abstract + Presentation)*
(online at: www.searchanddiscovery.com/documents/2013/50847saller/ndx_saller.pdf)
(3D seismic data y of Pleistocene shelf margin, slope and basin offshore E Kalimantan/ Makassar Straits. Clastic sequences on shelf dominated by progradational packages deposited during highstands and falling eustatic sea level. During last two sealevel lowstands (~18 and ~130 ka), coarse lastics generally not deposited in deep-water because lowstand deltas did not prograde over underlying shelf margin. During lowstand of ~240 ka, deltas prograded over previous shelf edge, and sand-rich sediments spilled onto slope. Channel-levee complexes on slopes where deltaic sediment supply was large (paleo-Mahakam River); incised valleys/canyons on slopes with limited clastic input. Basin floor deposits dominated by mass-transport complexes, suggesting slope valleys and canyons formed by mass failures of slope, not erosion associated with turbidite sands)

Saller, A. (2017)- Mixed carbonates and siliciclastics North of the Mahakam Delta, Offshore East Kalimantan, Indonesia. AAPG Ann. Conv. Exhib., Houston 2017, Poster, Search and Discovery Art. 1393, 5p. *(Abstract + Poster presentation)*
(online at: www.searchanddiscovery.com/documents/2017/51393saller/ndx_saller.pdf)
(For last 7 My carbonates mixed with siliciclastics N of Mahakam delta. Modern carbonates deposited locally N of delta while large amounts of clastics coming out of delta. Late Pleistocene carbonate mounds(on upthrown side of faults) and shelf margin carbonates (on underlying shelf margins) repeatedly grew during transgressions. During sea level highstands siliciclastics prograded across shelf, covering many carbonates. During last 7 My shelf margins generally backstepping landward N of Mahakam delta. Shales covering carbonates are downlapping packages, generally not effective seals)

Saller, A.H., T. Brown, R.B. Redhead, H.F. Schwing & J. Inaray (2000)- Deepwater depositional facies and their reservoir characteristics, West Seno Field, offshore East Kalimantan, Indonesia. AAPG Int. Conf. Abstracts, American Assoc. Petrol. Geol. (AAPG) Bull. 84, 9, p. 1484-1485. *(Abstract only)*
(Upper Miocene deepwater strata between 7500-8800' in West Seno Field about 27% sand, f-vf-grained and poorly sorted, deposited in middle- upper slope channel-levee complexes. Massive sands best reservoirs (av. porosity 29.3%, perm 630 mD), deposited as channel-fills or splay deposits. 'High resistivity-terrigenous' shales with thin silt and sand laminae interpreted as lowstand overbank deposits. Massive to burrowed, 'low-resistivity-hemipelagic' shales widespread and interpreted as transgressive and highstand deposits. Very thin sheets of coaly fragments locally abundant immediately above and within sand beds)

Saller, A. & I.N.W. Dharmasamadhi (2012)- Controls on the development of valleys, canyons, and unconfined channel-levee complexes on the Pleistocene slope of East Kalimantan. Marine Petroleum Geol. 29, 1, p. 15-34.
(Contrasting depositional patterns on Pleistocene deepwater slopes of offshore E Kalimantan: (1) in N dominated by deep valleys and canyons (relatively 'starved' for siliciclastic sediment); (2) central slope dominated by unconfined channel-levee complexes (large amounts of sediments from Mahakam Delta during Pleistocene lowstands)

Saller, A., I.N.W. Dharmasamadhi, T. Lilburn & R. Earley (2010)- Seismic geomorphology of submarine slopes; channel-levee complexes versus slope valleys and canyons, Pleistocene, East Kalimantan, Indonesia. In: L.J. Wood, T.T. Simo & N.C. Rosen (eds.) Seismic imaging of depositional and geomorphic systems, Gulf Coast Sect. SEPM, Ann. Perkins Research Conf. 30, Houston, p. 433-471
(3-D seismic images of Pleistocene deepwater slope channels E of Mahakam Delta. Channel-levee complexes developed where sediment supply was high; erosional channels where siliciclastic input rel. low)

Saller, A., R. Lin & J. Dunham (2006)- Leaves in turbidite sands: the main source of oil and gas in the deep-water Kutei Basin, Indonesia. American Assoc. Petrol. Geol. (AAPG) Bull. 90, 10, p. 1585-1608.
(Hydrocarbons in Kutei basin derived from land-plant source material. Leaf fragments in turbidite sandstones look like main source of deep-water oil and gas)

Saller, A. & J. Noah (2005)- Sequence stratigraphy of a linked shelf to basin floor system, Pleistocene, north Kutei Basin, East Kalimantan, Indonesia. Proc. Soc. Econ. Geoph. (SEG) 2005 Conv., Houston, 4p. *(Extended Abstract)*
(Pleistocene lowstand delta-canyon- basin-floor fan system, 240 ka old. The 18 and 130 ka lowstand deltas did not reach slope)

Saller, A., J.T. Noah, A.P. Ruzuar & R. Schneider (2004)- Linked lowstand delta to basin-floor fan deposition, offshore Indonesia; an analog for deep-water reservoir systems. American Assoc. Petrol. Geol. (AAPG) Bull. 88, 1, p. 21-46.
(3D seismic study of Pleistocene lowstand delta to basin floor deposition offshore E Kalimantan. Reflectors traced downslope from lowstand delta to basin-floor fan in last three Pleistocene cycles (each 110 k.y. in duration). During sea level lowstand at ~240 ka, delta prograded over previous shelf edge and sand-rich sediments spilled onto slope. Slope canyon connects 240-ka lowstand delta to coeval basin-floor fan. Canyon fill lower amalgamated channel complex and upper channel-levee complex. Lower part of basin-floor fan broad lobes with relatively continuous reflectors. Higher part sinuous channel-levee complex that prograded over lower fan and fed sheetlike lobes on outermost fan. Lowstand strata do not onlap slope but extend from last clinoforms of lowstand deltas)

Saller, A., J.T. Noah, R. Schneider & A.P. Ruzuar (2003)- Lowstand deltas and a basin-floor fan, Pleistocene, Offshore East Kalimantan, Indonesia. In: H.R. Roberts et al. (eds.) Shelf margin deltas and linked down slope petroleum systems, Proc. 23rd Annual Gulf Coast Chapter SEPM Bob F. Perkins Research Conf., p. 421-439.
(U Pleistocene N of Mahakam delta three cycles between ~18 and ~370 ka, defined on shelf by progradational packages, separated by parallel reflectors with carbonate buildups. During lowest of three cycles (~270-370 ka), lowstand delta prograded over underlying shelf margin, and sand-rich sediment spilled downslope, feeding slope-channel complex and basin-floor fan. Pleistocene cycles different from sequences/ systems tracts models defined in 1980s. Lowstand systems no onlap of slope, but generally parallel reflectors. Cycles best separated at tops of prograding packages (transgressive surfaces))

Saller, A., K. Werner, F. Sugiaman, A. Cebastiant, R. May, D. Glenn & C. Barker (2008)- Characteristics of Pleistocene deep-water fan lobes and their application to an upper Miocene reservoir model, offshore East Kalimantan, Indonesia. American Assoc. Petrol. Geol. (AAPG) Bull. 92, 7, p. 919-949.
(Late Pleistocene basin-floor fan seismic study to provide analog for deep-water fields off E Kalimantan. Pleistocene basin-floor fan ~170m thick, 22 km across, and with 18 lobes. Average lobe size 3.8x 7.2 km and 34m thick. Lobes contain sheetlike splays, distributary channels and younger incised channels. U Miocene Gendalo 1020 reservoir composed of turbidite sands draped over anticline. Gross reservoir interval 50-150m thick thin-bedded turbidite sands with net-to-gross ~50%)

Sardjono (1999)- Crustal structure of the Makassar Strait implication for geodynamics processes. Proc. 24th Ann. Conv. Indon. Assoc. Geophys. (HAGI), Surabaya, p. 3-10.

Sardjono (2000)- Gravity field and structure of the crust beneath the Makassar Strait, Central Indonesia. AAPG Int. Conf. Exhib., Bali. *(Abstract only)*
(Basement of Makassar Strait attenuated continental crustal rocks and probably also parts of upper mantle. Basins with up to 15,000m sediment and water depth of 2000-3000m. SEASAT data show trends and structure of crust, indicating stretching of continental crust in or before Miocene but tectonic polarity changed, probably in Late Miocene. Buckling-up of lower crustal rocks, suggests regional stretching ceased and regional compression prevailing until today. No figures)

Sassen, R. & J.A. Curiale (2006)- Microbial methane and ethane from gas hydrate nodules of the Makassar Strait, Indonesia. Organic Geochem. 37, 8, p. 977-980.
(White gas hydrate nodules in piston cores from Borneo side of deep water Makassar Strait. Hydrocarbon 99.9% methane and traces of microbial ethane, relatively depleted in 13C. Detrital higher-plant material likely source of microbial methane-ethane, formed by in-situ reduction of CO2 by extremophile bacteria adapted to

high pressure. Hydrate several 100m above base of gas hydrate stability zone. Nodular hydrate associated with seafloor authigenic carbonate and chemosynthetic clams characteristic of deep cold vent sites)

Satyana, A.H. (2015)- Rifting history of the Makassar Straits: new constraints from wells penetrating the Basement and oils discovered in Eocene section- implications for further exploration of West Sulawesi Offshore. Proc. 39th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA15-G-104, p. 1-35.
(New basement penetrations in N Makassar Straits by wells: Rangkong-1 and Kaluku-1 suggest basement of Makassar Straits is Paternoster-W Sulawesi microcontinent, thinned due to rifting from E-M Eocene to E Miocene, as response to back-arc rifting related to subduction roll back in SE Sundaland. Eocene rifted grabens and horsts were sites for shallow lacustrine sources, sandstone reservoirs, and traps)

Noble et al. (eds.) Proc. Deepwater and frontier exploration in Asia and Australasia symposium, Jakarta 2004, Indon. Petroleum Assoc. (IPA), p. 349-360.
(Basic paper on deep water channel-levee complexes)

Teas, P.A., J. Decker, A. Nurhono & A. Isnain (2004)- Exploration significance of high resolution bathymetry in the Makassar Straits. In: R.A. Noble et al. (eds.) Proc. Deepwater and frontier exploration in Asia and Australasia symposium, Jakarta 2004, Indon. Petroleum Assoc. (IPA), p. 389-397.
(Bathymetric map of Makassar Strait illustrates compression across basin, dominant over past ~15Ma, with surface anticlines on both sides of strait. High resolution resolves slumping of over-steepened forelimb and re-direction of depositional systems. Focused views show areas of active extensional faulting and folding, and submarine mud-volcanoes defining areas of active fluid venting. Tectonic lineaments expressed by changes in slope angle and degree of canyonization. Evidence for recent rapid uplift at N margin of Makassar Strait vs. aggrading canyon systems on W margin)

Sherwood, P., S. Algar, G. Goffey, I. Busono, J.N. Fowler, J. Francois, M.J. Smith & A. Strong (2001)- Comparison of recent and Mio-Pliocene deep water deposits in the Kutei Basin, East Kalimantan. Proc. 28th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 423-438.
(Deepwater Kutei Basin (Makassar Straits) seismic examples of slope and basin floor sediments)

Siringoringo, L.P. & D. Noeradi (2016)- The Paleogene tectonostratigraphy of northern part Masalima Trench Basin. J. Geoscience Engineering Environm. Technol. (JGEET) 1, 1, p. 7-24.
(online at: http://journal.uir.ac.id/index.php/JGEET/article/view/2/2)
(N part of Masalima Trench Basin in S end of Makassar Straits and extends to NE part of Java Sea. N part of Masalima Trench Basin formed by NE-SW normal faults with early syn rift sediment (M Eocene), deep marine late syn rift (Late Eocene- E Oligocene) and deep marine post rift (E Oligocene- E Miocene). Basement in 'Alpha well' red radiolaria chert, presumably tectonic melange, in 'Beta well' (on high) metasediments with K-Ar age of 131 ± 7 Ma (Lower Cretaceous))

Situmorang, B. (1977)- The Makassar Trough regional geology and hydrocarbon prospects. Lemigas Scientific Contr. 1, 1, p. 3-20.
(N and S Makassar basins originated as continental rift in triple-junction rift-system. Classified as marginal sea, flanked in W by Asian continental margin and by volcanic arc of Sulawesi in E. Strongly positive gravity anomalies suggest it is underlain by oceanic crust. Melawi-Ketungau basins of Kalimantan possible third arm of triple junction rift system. Possible presence of turbiditic reservoir rocks, and favorable conditions for accumulation of organic matter during initial rifting stage of seafloor spreading suggest Makassar basins may be highly prospective)

Situmorang, B. (1982)- The formation and evolution of the Makassar Basin, Indonesia. Ph.D. Thesis Chelsea College, University of London, p. 1-313. *(Unpublished)*

Situmorang, B. (1982)- The formation of the Makassar Basin as determined from subsidence curves. Proc. 11th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 83-107.
(Subsidence of Makassar Basin compatible with McKenzie stretching model. Basin formation started with rifting in E-M Eocene or earlier, continuing until E Miocene. Rifting ceased by end of E Miocene, and since then >6 km of sediments deposited across basin without significant deformation. Oceanic crust will occur at stretching factor of 2.9, corresponding to present water depth of >3.2 km. No such water depths, so basin underlain by thinned continental crust (but includes sediment thickness?; JTvG))

Situmorang, B. (1984)- Formation, evolution, and hydrocarbon prospects of the Makassar Basin, Indonesia. In: S.T. Watson (ed.) Trans. Third Circum-Pacific Energy and Mineral Resources Conference, Honolulu 1982, American Assoc. Petrol. Geol. (AAPG), p. 227-232.
(Makassar Straits subsidence explained by stretching of continental crust by factor of 2.0- 2.9. Initially fault-controlled subsidence started in E-M Eocene, or possibly earlier. Active crustal stretching lasted until end of E Miocene; thermally controlled subsidence since M Miocene. Predicted crustal thickness in central part of basin 15 km. Assuming heatflow of 1.6 HFU Pre-Lower Miocene reached maturity for hydrocarbon generation. With seismic profile 605)

Situmorang, B. (1987)- Seismic stratigraphy of the Makassar Basin. Lemigas Scientific Contr. Petrol. Science Techn. 11, 1, p. 3-38.
(Three main discontinuity surfaces in Cenozoic sediments of seismic lines across N and S Makassar Straits basin. Rel. poor data)

Situmorang, B. (1989)- Crustal structure of the Makassar basin as interpreted from gravity anomalies: implications for basin origin and evolution. Lemigas Scientific Contr. 13, 1, p. 10-24.
(Gravity, well subsidence data and seismic data of (South) Makassar Basin interpreted to suggest it is underlain by highly attenuated continental crust with average thickness of 15km (but central zones of line A-A' in South Makassar basin E of Paternoster Platform modeled as ~8-9 km crustal thickness= oceanic crust thickness?; JTvG). Continental rifting during M Eocene- E Miocene, followed by thermal subsidence)

South, D., G. Toxopeus & B. Myhren (2013)- Karama PSC well results-a lesson learned on provenance and seismic imaging of deepwater systems. Proc. 37th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA13-G-070, p. 1-7.
(Karama block off W Sulawesi in N Makassar Strait multiple prospects (bright seismic amplitudes in Late Miocene- E Pliocene section in young foldbelt structures). Sediments sourced from Sulawesi hinterland, with deep-water fans and debris flow identified from 3D seismic data. Three wells drilled on interpreted sand fairways showed bright seismic amplitudes not sand but siltstones, greywacke sandstones with no to poor reservoir properties)

Subroto, E. A., D. Noeradi, A. Priyono, H.E. Wahono, E. Hermanto & M. Syaifuddin (2007)- Preliminary study on Paleozoic and Mesozoic source rocks in the frontier offshore South Makassar basin, Indonesia. In: Y. Wang & T.D. Bullen (eds.) Proc. 12th Int. Symposium on Water-rock interaction, Kunming 2007, Taylor and Francis, London, 2, Chapter 188, p. 905-908.
(Oil and and gas known from onshore and offshore S Makassar Basin, but source rocks not established yet. Most likely source in basin Eocene- Oligocene sediments and, possibly also Miocene. Samples from exploration wells suggest most samples have not reached oil window. Basin modeling suggest Eocene sediments mature from peak oil to dry gas window, Miocene sediments range from barely mature to peak of oil generation (Misleading title?; JTvG))

Tanos, C.A. (2011)- Diagenetic effects on reservoir properties in a carbonate debris deposit: case study in the Berai Limestone, ñMò Field, Makassar Strait, Indonesia. Bull. Earth Sci. Thailand 4, 2, p. 17-24.

(online at: www.geo.sc.chula.ac.th/BEST/volume4/number2/3_Chrisna_Asmiati_Tanos_BEST_4_2_p%2017-24.pdf)
(S Makassar Straits 'M' gas field (= Ruby/ Makassar Straits) developed in Oligocene- E Miocene Berai Fm carbonate slope debris reservoirs. With multistage diagenetic and tectonic evolution, incl. phase of late deep burial leaching)

Tanos, C.A., J. Kupecz, A.S. Hilman, D. Ariyono & I.L. Sayers (2013)- Diagenesis of carbonate debris deposits from the Sebuku Block, Makassar Strait, Indonesia. Proc. 37th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA13-G-159, p. 1-18.
(Ruby Field, SW Makassar Strait, will be developed from Late Oligocene carbonate debris flow reservoirs. Reservoir facies mainly matrix- and clast-supported breccias. Debris deposits correspond to two global sea level lowstands (Chattian-1; 28 Ma) and Burdigalian-1; 20 Ma). Adjacent feature (NW Ruby-1) unexpectedly dry, and, unlike Ruby Field, did not undergo extensive late dissolution, and may also have been isolated from lateral hydrocarbon migration)

Tanos, C.A., J. Kupecz, S. Lestari, J.K. Warren & A. Baki (2012)- Depositional and diagenetic effects on reservoir properties in carbonate debris deposits: comparison of two debris flows within the Berai Formation, Makassar Strait, Indonesia. AAPG Int. Conf. Exhib., Singapore 2012, Search and Discovery Art. 50768, p. (*Presentation*)
(online at: www.searchanddiscovery.com/documents/2012/50768tanos/ndx_tanos.pdf)
(After successful gas discovery and appraisal of Makassar Straits field (= Ruby) in Late Oligocene Upper Berai Fm bathyal debris flow carbonate reservoir in Pangkat Graben, S Makassar Basin, a subsequent exploration well in adjacent NW-1 feature was unexpectedly dry. Differences in post-depositional diagenesis explain better reservoir quality in Ruby field)

Teague, R., J.T. Noah, R. Redhead, M. Swanson, T. Brown & N. Briedis (1999)- Merah Besar and West Seno Field discoveries, Makassar Strait, East Kalimantan, Indonesia. AAPG Int. Conf. Exh. Abstracts, American Assoc. Petrol. Geol. (AAPG) Bull. 83, 8, p. 1343.
(First Indonesia deep water discoveries by Unocal in 1996 and 1998 in toe-thrust anticlines with stratigraphic trapping components. Merah Besar in 1700' - 2700' of water, 40 km2, productive reservoirs between 4000-9500' TVD in Pliocene and Upper Miocene upper to mid-slope turbidite channel-levee sandstones. West Seno in 2400- 3200' of water, ~70 km2, with hydrocarbons between 7000' -9500' TVD, where Upper and M Miocene sandstones are faulted and stratigraphically trapped in updip position. Sandstones rel. continous and interpreted as amalgamated turbidite channels capped by hemipelagic shales. Porosity 24-32%, permeability 150-1500 md. Sandstones quartzose and mainly fine grained. Miocene oils and Pliocene and Miocene gases derived from similar source facies of land plant-dominated organic material. Oils API gravity 35-46 degrees)

Thompson, P., J.J. Hartman, M.A.A. Anandito, D. Kumar et al. (2009)- Distinguishing gas sand from shale/brine sand using elastic impedance data and the determination of the lateral extent of channel reservoirs using amplitude data for a channelized deepwater gas field in Indonesia. The Leading Edge 28, 3, p. 312-317.
(Chevron Sadewa Field 2002 discovery in Makassar Straits NE of Mahakam Delta, ~5 km from Kalimantan shelf edge in water depths of 1500-2500'. Reservoirs Late Miocene deep water channel sandstones. Nine wells drilled. Very expensive development. Propose using elastic impedance data for distinguishing gas sands)

Untung, M., J. Taruno, A. Maulana, P. Kridoharto & S. Sukardi (1985)- Explanatory note on preliminary aeromagnetic map of the Makassar Strait. Proc. 20th Sess. Comm. Co-ord. Joint Prospecting Mineral Resources in Asian Offshore Areas (CCOP), Kuala Lumpur 1983, 2, Tech. Repts., p. 199-209.
(Aeromagnetic map over Makassar Straits shows two areas of different character, separated by Paternoster Arch: (1) high anomalies of quiet magnetization in North Makassar Basin (interpreted to be oceanic crust) and (2) low to high anomalies of noisy character in South Makassar Basin)

Van Gorsel, J.T. & E.C. Helsing (2014)- A Late Oligocene drowned pinnacle reef in deepwater Makassar Straits. Berita Sedimentologi 29, p. 116-122.
(online at: www.iagi.or.id/fosi)

(Carbonate seamount with 320-350m of relief in 2050m deep water of S Makassar Straits is Late Oligocene-age pinnacle reef, which drowned in latest Oligocene time, based on presence of Miogypsinoides cf. bantamensis near crest and Spiroclypeus and Neorotalia mecatepecensis deeper in section. Carbonate buildup with ferro-manganese cement, representing >20 Million years of deep water seafloor exposure and non-deposition)

Visser, K., R. Thunell & M.A. Goni (2004)- Glacial- interglacial organic carbon record from the Makassar Strait, Indonesia: implications for regional changes in continental vegetation. Quaternary Science Reviews 23, 1-2, p. 17-27.
(Climate in W Pacific Warm Pool 3-4°C colder during glacial periods. Core MD9821-62 from Makassar Strait suggests vegetation on Borneo and other islands did not significantly change from tropical rainforest during last two glacial periods. This supports hypothesis that winter monsoon increased in strength during glacial periods, allowing Indonesia to maintain high rainfall despite cooler conditions. Organic matter mixed marine-terrestrial; higher TOC during glacials due to enhanced erosion of continental shelves)

Wijaya, P.H. & D. Kusnida (2009)- Tinjauan geotektonik Selat Makassar Utara, implikasinya terhadap potensi hidrokarbon laut dalam cekungan Kutai, Kalimantan Timur. J. Geologi Kelautan 7, 3, p. 109-121.
(online at: http://ejournal.mgi.esdm.go.id/index.php/jgk/article/view/176/166)
('The geotectonic views of the North Makassar Straits, its implications for the potential of marine hydrocarbons in the Kutai basin, East Kalimantan'. Literature review of geotectonic evolution of Makassar Straits and potential for hydrocarbons in deepwater Makassar Straits in toe thrusts around Mahakam Delta. Seismic character, water depths, gravity modeling, etc. suggest much of Makassar Straits, including the Mahakam Delta, underlain by oceanic crust, as continuation of Eocene spreading in Celebes Sea)

(Crustal extension important in Neogene development of Sulawesi. North Arm with Eocene- Lower Miocene basalts intercalated with radiolarian chert and volcaniclastics, intruded by granitoids with zircon ages from~9.4- 8.2 Ma. Beneath these rocks is Malino Metamorphic core complex quartzo-feldspathic schist-gneiss with zircon rim ages of ~15.4 Ma, surrounded by discontinuous greenschist carapace, intruded by granitoids with ages of 4.85- 3.78 Ma. Late stage exhumation by high angle oblique normal faults between ~3.3- 1.4 Ma. E Pliocene- E Pleistocene sediments crosscut by normal faults. Two phases of extension in N Sulawesi, M Miocene and Late Pliocene-Pleistocene)

Advokaat, E., R. Hall, L. White, I.M. Watkinson, A. Rudyawan & M.K. BouDagher-Fadel (2017)- Miocene to recent extension in NW Sulawesi, Indonesia. J. Asian Earth Sci. 147, p. 378-401.
(online at: http://searg.rhul.ac.uk/pubs/advokaat_etal_2017%20Extension%20North%20Sulawesi.pdf)
(Malino Metamorphic Complex (MMC) in W part of N Arm of Sulawesi previously thought to be metamorphic complex exhumed in E-M Miocene. New data suggest MMC metamorphic core complex underwent E-M Miocene extension, but no exhumation at this time: (1) Pliocene undeformed granitoids intrude MMC indicating complex still at depth and (2) Pliocene- Pleistocene cover sequences do not contain metamorphic

detritus. Second phase of extensional uplift with brittle faulting from Late Miocene-Pliocene onwards, with MMC exhumation (synchronous exhumation of adjacent Palu Metamorphic Complex in W Sulawesi, and rapid offshore subsidence in Gorontalo Bay). Linked to N-ward slab rollback of S-subducting Celebes Sea since Pliocene, and ongoing at present day)

Barber, A.J. (1996)- Multiple collisions on the southeastern margin of Sundaland: the tectonic evolution of Sulawesi. Warta Geologi (Newsl. Geol. Soc. Malaysia) 22, 4, p. 300-301. *(Abstract only)*
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm1996004.pdf)
(Sundaland constructed since Late Paleozoic by collisions of continental fragments. In E Cretaceous SE margin of Sundaland lay in Borneo; subduction and accretion added oceanic and micro continental material to this margin. In W Sulawesi oldest basement rocks are ocean floor materials in accretionary complex, with components carried down deep in subduction zone (eclogites, gneisses and glaucophane schists with cooling ages of 132-113 Ma (E Cretaceous). After uplift and erosion, Late Cretaceous subsidence and development of forearc basin over accretionary complex, with deposition of cherts and turbidites. In Eocene area stabilised as part of Sundaland continental margin, with development of rifts. C Sulawesi composed of rocks of oceanic and

continental origin now metamorphosed in amphibolite, greenschist and glaucophane schist facies, overlain by melange, then by major ophiolite complex of East Arm. Amphibolite and greenschist facies rocks formed by W-ward subduction of microcontinental fragment and metamorphosed in E Cretaceous, at same time as basement in W Sulawesi. Glaucophane schist metamorphism affects earlier metamorphic rocks and melange, which is overlain to E by high-T metamorphic sole beneath E Sulawesi Ophiolite. Melange formation and metamorphism due to mid-oceanic subduction towards E. Subduction ceased at 28 Ma (Oligocene), when Sundaland ran into subduction zone and ophiolite obducted onto continental margin. W-ward subduction then commenced beneath E margin of ophiolite, terminating in M Miocene when Banggai-Sula microcontinent ran into subduction zone. Banggai-Sula originated as fragment of Australia, separated in Jurassic, carried W along Sorong Fault Zone. Collision zone in E Arm is marked by imbrication of Banggai-Sula continental margin sediments with slices of ophiolite. Metamorphic rocks of C Sulawesi were thrust across W Sulawesi, and uplifted blocks of basement were thrust W-wards across Eocene-M Miocene carbonate platform. Downgoing continental rocks subducted beneath W Sulawesi gave rise to volcanic arc with volcanic rocks geochemical signature of Australian origin)

(K-Ar ages for>50 igneous rocks from onshore Philippines, N Borneo (Sabah) and N Sulawesi. Ages range from 32 Ma to near 0 Ma. Generally calc-alkaline affinity with some shoshonitic high-K basalts. Two types of island arcs (1) related to progressive closing of Celebes and Sulu marginal basins and (2) arcs of Philippine Sea Plate. Includes radiometric dates of Sabah Dent- Semporna Peninsula (9- 13 Ma), Sulu Sea/ Cagayan Ridge (ODP Sites 769/771: ~14-21 Ma), Kinabalu Intrusives (6.4- 6.8 Ma), N Sulawesi (Gorontalo area volcanics: 4.1- 8.9 Ma and 18.2- 22.3 Ma)

Bergman, S.C., D.Q. Coffield, J.P. Talbot & R.A. Garrard (1996)- Tertiary tectonic and magmatic evolution of western Sulawesi and the Makassar Strait, Indonesia: evidence for a Miocene continent-continent collision. In: R. Hall & D.J. Blundell (eds.) Tectonic evolution of Southeast Asia, Geol. Soc., London, Spec. Publ. 106, p. 391-429.
(W Sulawesi three Neogene N-S domains, from W to E: (1) active foldbelt with Pliocene- Miocene volcanogenic rocks in W-vergent thrusts, extending into Makassar Strait; (2) deformed submarine Miocene (av. age 8 Ma) arc, built on Oligocene-Eocene clastics and carbonate platform with Mesozoic basement thrust over E margin; (3) accreted pre-Eocene age ophiolite between Latimojong basement block and Bone Bay, obducted in Late Oligocene- Miocene. M Miocene- Pliocene (3-18 Ma) volcano-plutonic complex, with melts sourced from Late Proterozoic- E Paleozoic, tied to continent-continent collision of W-vergent Australian-New Guinea plate subducting under E-most Sundaland. Makassar Strait is foreland basin flanked by Neogene thrust belts, not Paleogene rift. E Sulawesi ophiolite extends into W Sulawesi, suggesting Bone Bay resulted from collapse of over-thickened Miocene orogen)

Berry, R.F. & A.E. Grady (1987)- Mesoscopic structures produced by Plio-Pleistocene wrench faulting in South Sulawesi, Indonesia. J. Structural Geol. 9, p. 563-571.
(Bantimala and Barru metamorphic complexes of S Sulawesi bounded in W by E-dipping thrust faults. Composed of glaucophane schists, serpentinites, etc., overlain by >750m of Cretaceous clastics. Area

dominated by Plio-Pleistocene NNW-striking sinistral wrench faults, result of N-ward movement of Banda Sea microplate with respect to W Indonesia)

Bohnke, M., M. Brocker, A. Maulana, R. Klemd, J. Berndt & H. Baier (2019)- Geochronology and Zr-in-rutile thermometry of high-pressure/low temperature metamorphic rocks from the Bantimala complex, SW Sulawesi, Indonesia. Lithos 324-325, p. 340-355.
(online at: https://www.sciencedirect.com/science/article/pii/S0024493718304419)
(Multipoint Rb–Sr mineral isochrons of highP/ low T eclogites and glaucophane-rich rocks from Bantimala Complex, SW Sulawesi narrow range of white mica ages (130-120 Ma), interpreted to postdate peak-HP conditions. Luk Ulo-Java ages of ~118 Ma slightly younger (Hoffmann et al. 2019), but may still be in same subduction complex. Rare zircons in glaucophane-rich rocks indicate Late Triassic- E Jurassic protolith ages (~205-185 Ma). Metamorphic zircon rims mostly 135-110 Ma ages. Older zircons (2.55-1.4 Ga, 400-260 Ma) probably from subducted sediments incorporated in mafic melts)

('A carbonate platform of Rhaetian age in Central-East Sulawesi (Kolonodale region'. Widespread outcrops of ~150m of white latest Triassic reefal carbonates S and SW of Kolonodale (below E Sulawesi ophiolite terrane?). Limestones range from boundstone to grainstone. Non-skeletal grains mainly peloids and some ooids and intraclasts. Skeletal grains molluscs, green algae (including dasycladaceans), echinoderms and benthic foraminifera (Aulotortus spp., Auloconus, Triasina hantkeni) and locally also brachiopods, coral clusters. Limestones can be correlated with U Triassic limestones of Tokala Mts of Sulawesi East Arm)

Costa, K.M., J.M. Russell, H. Vogel & S. Bijaksana (2015)- Hydrological connectivity and mixing of Lake Towuti, Indonesia in response to paleoclimatic changes over the last 60,000 years. Palaeogeogr. Palaeoclim. Palaeoecology 417, p. 467-475.
(Sediment geochemistry of cores from Lake Towuti in C Sulawesi records paleoclimate changes over last 60 ka. During Last Glacial Maximum no changes in sediment provenance, despite drier climate, but trace elements suggest decrease in weathering intensity, likely in response to decreased precipitation and temperature)

Cottam, M.A., R. Hall, M. Forster & M. Boudagher Fadel (2011)- Basement character and basin formation in Gorontalo Bay, Sulawesi, Indonesia: new observations from the Togian Islands. In: R. Hall, M.A. Cottam & M.E.J. Wilson (eds.) The SE Asian gateway: history and tectonics of Australia-Asia collision, Geol. Soc. London, Spec. Publ. 355, p. 177-202.
(Togian islands stratigraphy includes Walea Fm pillow basalts and volcanic breccias of unknown age, overlain by late Middle Miocene Peladan Fm limestone, overlain by Late Miocene- E Pliocene Bongka Fm/ Celebes Molasse and uplifted ?Pleistocene reef terraces. Field relationships indicate latest Miocene- Pliocene age for inception of Gorontalo Bay basin. Young medium-K to shoshonitic volcanism in Togian Islands not due to subduction but reflects crustal thinning and extension in Pliocene- Pleistocene. Extension continuing today. Extension and subsidence driven by rollback of subduction hinge at N Sulawesi Trench.)

Crotty, K.J. & D.W. Engelhardt (1993)- Larger foraminifera and palynomorphs of the upper Malawa and lower Tonasa Formations, southwestern Sulawesi Island, Indonesia. In: T. Thanasuthipitak (ed.) Int. Symposium Biostratigraphy of mainland Southeast Asia: facies and paleontology (BIOSEA), Chiang Mai 1993, p. 71-82.
(SW Sulawesi M Eocene coal-bearing Malawa Fm clastics with pollen Retitribrevicolporites matamanadhensis and dinoflagellates Muratodinium fimbriatum and Homotryblium floripes. Overlying clastics/ limestones Late Eocene with Verrucatosporites usmensis, Nummulites javanus (Ta3?) and Pellatispira- Biplanispira (Tb), Discocyclina and Asterocyclina. Overlain by ~120' thick basal dolomitic member of E Oligococene Tonasa Lst with Coskinolina, Praerhapidionina, arenaceous foraminifera and miliolids, overlain by thin Tc with Nummulites fichteli and Td with same + Eulepidina, Austrotrillina striata. Near top of Tonasa quarry Late Oligocene/ Te1-4 with Nephrolepidina, Spiroclypeus and Heterostegina borneensis. No miogypsinids seen)

Cucci, M.A., R.A. Garrard & M. Golborne (1994)- The Early Tertiary rift basins of offshore South Sulawesi, Indonesia. AAPG Ann. Mtg., Denver *(Abstract)*
(Offshore S Sulawesi Paleogene rift system activated and failed twice. Initial rifting Late Paleocene-E Eocene, with N-S oriented sags on Cretaceous platform with Langi Fm volcanics. By M Eocene rifting failed and uplift/ erosion formed major unconformity. Second rift event M Eocene, close to earlier 'sags'. N-S orientation, from off S Sulawesi to near Sabalana Island at intersection with E-W trending Kangean-Lombok rift system. M Eocene terrestrial-lacustrine Malawa/Toraja Fms overlain by fluvio-deltaic deposits. In Late Eocene rifting ceased, leaving extensive shelfal areas isolated from Sulawesi sediment supply. Transgression initiated vast Tonasa/ Makali Fm carbonate platform with localized reefal buildups. Late Miocene carbonates gave way to siliciclastics (Camba Fm), derived from establishment of major magmatic belt. Late Tertiary compressional tectonics inverted many Paleogene rifts to form classic 'Sunda- type' folds)

Dam, R.A.C., J. Fluin, P. Suparan & S. van der Kaars (2001)- Paleoenvironmental developments in the Lake Tondano area (N-Sulawesi, Indonesia) since 33,000 yr B.P.. Palaeogeogr. Palaeoclim. Palaeoecology 171, p. 147-183.
(Lake Tondano at 680m above SL. Lake levels rose and fell. Late Pleistocene phase with lower precipitation and lower temperatures. Progressive deforestation of Tondano upland)

Darman, H. (2011)- Seismic expression of North Sulawesi subduction zone. Berita Sedimentologi 22, p. 5-8.

Effendi, A.C. & S.S. Bawono (1997)- Geologic map of the Manado quadrangle, North Sulawesi, 2nd Ed.. Geol. Res. Dev. Centre (GRDC), Bandung.

(Geologic map of NE tip of North Arm of Sulawesi. Common E Miocene- Recent volcanics and volcanoclastics and associated limestones. Volcanic arc formed as response to subduction from N Sulawesi subduction zone and East (E Sangihe subduction zone))

Egeler, C.G. (1947)- Contribution to the petrology of the metamorphic rocks of Western Celebes. In: H.A. Brouwer (ed.) Geological Explorations of the Island of Celebes, North Holland Publishing Co., p. 177-346.
(Also Thesis University of Amsterdam, 1946, p. 1-165. Descriptions of metamorphic and igneous rocks from N Part of western Central Sulawesi and S part of Sulawesi 'neck', collected by Brouwer in 1929. Widespread young 'alpine' granodioritic intrusions of W Sulawesi caused intense plutonic contact metamorphism, which was superimposed over older regional metamorphism)

Egeler, C.G. (1949)- On amphibolitic and related rocks from western Celebes and the southern Sierra Nevada, California. Proc. Kon. Nederl. Akademie Wetenschappen, Amsterdam, 51, 1, p. 100-105.
(On similarities between metamorphic rocks of Sulawesi and Sierra Nevada, California)

Egeler, C.G. (1949)- On metamorphic rocks from the island of Kabaena in the East-Indian Archipelago. Proc. Kon. Nederl. Akademie Wetenschappen, Amsterdam, 52, 5, p. 551-562.
(online at: www.dwc.knaw.nl/DL/publications/PU00018668.pdf)
(Petrographic descriptions of metamorphic rocks collected by Brouwer in 1929: hornfels, mica-schists, gneiss, amphibolite, amphibolite schist and crystalline limestones. Kabaena high-grade regional metamorphic schists considered to be older than ophiolitic rocks, similar to SE Sulawesi, but not affected by younger glaucophanitic metamorphism as seen in E Sulawesi (but De Roever (1953) did report glaucophane schist from Kabaena; JTvG). No locality maps or geologic context)

Elburg, M. & J. Foden (1998)- Temporal changes in arc magma geochemistry, Northern Sulawesi, Indonesia. Earth Planetary Sci. Letters 163, p. 381-398.
(N Sulawesi Sangihe Arc Late Miocene- Recent volcanics geochemical change through time. Oldest suites mantle source with previous event of melt extraction. Modern lavas, especially volcanic centres far from trench indicate subduction zone component dominated by melt of sedimentary origin. Change from fluid-dominated to melt-dominated subduction zone component may be related to collision between Halmahera and Sangihe arcs. These changes appear superimposed on variable parent magma composition)

Elburg, M. & J. Foden (1999)- Sources for magmatism in Central Sulawesi: geochemical and Sr-Nd-Pb isotopic constraints. Chemical Geology 156, p. 67-93.
(M Miocene- Quaternary magmatism in C West Sulawesi distinct subduction signature. Isotopic signature of lamprophyres interpreted as mixed mantle source with contribution from old sub-continental lithospheric source, from sliver of Australian continent thrust under C Sulawesi. Felsic magmatism likely reflects high degrees of crustal contamination or intracrustal melting)

Elburg, M.A. & J. Foden (1999)- Geochemical response to varying tectonic settings: an example from Southern Sulawesi (Indonesia). Geochimica Cosmochimica Acta 63, p. 1155-1172.
(S arm Sulawesi active continental margin from ~60 to 10 Ma, when it collided with Buton microcontinent. Pre-collisional geochemical signature typical of arc volcanics. Syn-collisional samples more enriched isotopic signatures and K-rich, interpreted to reflect larger contribution from subducted sediments, added to mantle wedge as silicic melt. Magmatism that postdates 10 Ma collision reflects melting of subduction-modified mantle with significant contribution from subcontinental lithospheric mantle)

Elburg, M.A., V.S. Kamenetsky, I. Nikogosian, J. Foden & A.V. Sobolev (2006)- Co-existing high- and low-calcium melts identified by mineral and melt inclusion studies of a subduction-influenced syncollisional magma from South Sulawesi, Indonesia. J. Petrology 47, 12, p. 2433-2462.
(online at: https://academic.oup.com/petrology/article/47/12/2433/1564500)
(Mineral and melt inclusions in olivines from Late Miocene (6-9 Ma) mafic silica-undersaturated ultra-potassic volcanic rocks with 'continental' Sr isotopic characteristics from southern W Sulawesi Volcanic Province

indicate that two distinct melts contributed to its petrogenesis. High-CaO melt typical for subduction-related volcanic rocks, low-CaO melt does not have any obvious rock equivalent)

Elburg, M.A., T. Van Leeuwen, J. Foden & Muhardjo (2002)- Origin of geochemical variability by arc-continent collision in the Biru Area, Southern Sulawesi (Indonesia). J. Petrology 43, 4, p. 581-606.
(online at: https://academic.oup.com/petrology/article/43/4/581/1473969)
(Two main Tertiary volcanic episodes in SW Sulawesi: (1) M-L Eocene (~50 Ma) calc-alkaline Langi volcanics, (2) late Early Miocene calc-alkaline and M-L Miocene (15-6.3 Ma) potassic arc volcanics, both presumably related to W-dipping subduction. Also 1.8 Ma volcano farther S, not related to subduction? Miocene volcanics more heterogeneous after Buton microcontinent collision at ~15 Ma. Isotopic ratios more 'continental' 4 My after collision)

Elburg, M., T. van Leeuwen, J. Foden & Muhardjo (2003)- Spatial and temporal isotopic domains of contrasting igneous suites in western and Northern Sulawesi, Indonesia. Chemical Geology 199, p. 243-276.
(Paleocene- Pliocene magmatism in NW Sulawesi progression from Older Series with calc-alkaline/ tholeiitic signatures (51-17 Ma) to Younger Series of mafic-intermediate high-K magmas (~14-5 Ma) and felsic K-rich calc-alkaline magmas (9-2 Ma). Younger felsic magmatism reflects melting of Australian origin continental crust. Geochemical progression similar to C Sulawesi and explained by oceanic plate subduction followed by melting of underthrust sliver of Australian microcontinent, the size of which can be estimated from extent of low-Nd-isotope magma (~4°S to 1°N). Underthrusting must have happened prior to 14 Ma, indicating it cannot be equated to Sulawesi- Sula platform collision at 5 Ma. While subduction beneath W Sulawesi ceased prior to onset of potassic magmatism, it continued in N Sulawesi producing calc-alkaline suites)

Erlinghagen K.P. (1991)- Petrogenese und geodynamische Entwicklung der Subduktions-Metamorphite von Zentral-Sulawesi, Indonesien. Goettinger Arbeiten Geol. Pal. 52, 103p.
('Petrogenesis and geodynamic development of subduction metamorphics of Central Sulawesi'. Analyses of metamorphic rocks and minerals from NE of Lake Poso and W-NW of Poso town. High-pressure metamorphic rocks of C Sulawesi formed as result of oblique subduction in WNW-dipping subduction zone. Metamorphic grade increasing P and T from E to W: lawsonite-blueschist facies of Taripa belt grade W-ward into epidote-blueschist and eclogite facies of Tineba belt. Max. P-T conditions ~11 kbar/ 400-450°C (Taripa) and ~13 kbar/500-570°C (~45km depth; Tineba). Age of peak metamorphism ~60-65 Ma (Paleocene), followed by rapid cooling in Eocene. K-Ar cooling ages of phengite in garnet-mica schist 38.8 Ma (Late Eocene), silicate marble 50.2 Ma (E Eocene). Late metamorphic overprint of lawsonite-blueschist zone suggested by K-Ar ages around 19 Ma, tied to age of intrusives in W and onset of Banggai-Sula collision)

('Age zonation in granitic rocks of Polewali, S Sulawesi'. K-Ar ages of biotite in Polewali granite 3.1- 14.0 Ma suggest age zonation of ~3.1-3.5 Ma at outside, 6.1-9.8 Ma in middle and 14.0 Ma in center. Ages from hornblende and biotite from Riso syenite 4.5- 6.75 Ma)

Grainge, A.M. & K.G. Davies (1983)- Reef exploration in the East Sengkang Basin, Sulawesi. Proc. 12th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 207-227.
(East Sengkang Basin Late Miocene reefs in outcrop and as shallow gas-bearing Late Miocene reefs in N part of basin. Four accumulations with ~0.75 TCF of dry gas in place at average depth 700m. Kampung Baru is largest field and contains over half the total. Reservoir quality excellent. Gas probably generated in W Sengkang Basin and sub-sequently migrated into E Sengkang Basin)

Grainge, A.M. & K.G. Davies (1985)- Reef exploration in the East Sengkang Basin, Sulawesi, Indonesia. Marine Petroleum Geol. 2, p. 142-155.
(Shallow, gas-bearing Upper Miocene reefs in N part Sengkang basin, with Kampung Baru as largest field. Lower Miocene mudstones and limestones unconformable over Eocene volcanics acoustic basement. Two M Miocene periods of deformation and erosion. Late Miocene widespread carbonate deposition with platform limestones and pinnacle reef complexes. Reef growth ceased at end Miocene and clastic sedimentation covered irregular limestone surface. Walanae sinistral strike-slip fault zone separates E and W Sengkang Basins)

Gunawan, W. (1999)- Structure, stratigraphie et evolution de la partie centrale de Sulawesi (Indonesie orientale). Doct. Thesis Universite de Aix-Marseille, p. 1-283. *(Unpublished)*
(Sulawesi is area of collision between Eurasian and Gondwanan blocks. Three main events: (1) collision of Asia- Banda Blocks (= E Sulawesi) in Late Oligocene, (2) collision of Banda- Lucipara blocks in M Miocene and (3) collision of Banggai-Sula and Sulawesi in M Pliocene. C Sulawesi marks collision between Asia and Banda blocks, with obduction of ophiolite nappe of Asian origin over E Sulawesi block. E Sulawesi block sedimentary cover starts with Triassic reefal/ platform carbonates followed by Early Jurassic platform interior carbonates, Lower Cretaceous radiolarites and Upper Cretaceous-Oligocene pelagic limestones. High P- low T metamorphism during W-directed subduction in Early Oligocene. Western active margin has substrate metamorphosed in Aptian- Albian, overlain by Upper Cretaceous- Pliocene volcano-sedimentary formations, and deforemed by thrusting during Oligocene collision, possibly followed by a Middle Miocene event also known from Buton island)

Guntoro, A. (1996)- Seismic interpretation and gravity models of Bone Bay in relation to its evolution. Proc. 25th Ann. Conv. Indon. Assoc. Geol. (IAGI), Bandung, 3, p. 349-369.

Guntoro, A. (1997)- Stratigrafi dan evolusi tektonik Pulau Tanahjampea dan sekitarnya, Kabupaten Selayar, Sulawesi Selatan. Berita Sedimentologi 4, p. 9-17.
('Stratigraphy and tectonic evolution of Tanahjampea Island and surroundings, Selayar District, S Sulawesi'. Oldest rocks Eocene volcanic breccia (part of Langi volcanics of S Sulawesi?), overlain by E Miocene limestone with Lepicyclina (part of Tonasa Lst of Sulawesi?), Pleistocene volcanic breccia)

Guntoro, A. (1997)- Preliminary study of the geology and tectonics of the Flores Sea islands, South Sulawesi. Proc. 26th Ann. Conv. Indon. Assoc. Geol. (IAGI), Jakarta, p. 291-313.
(Islands S of SW Sulawesi/ Flores Sea (Selayar, Bonerate and Kalaotoa groups) poorly known. Similar stratigraphy to SW Sulawesi. Extensive volcanic and tectonic activity since Eocene. Tanahjampea and Tanahmalala islands mainly SW Sulawesi-like granite, also Eocene and M-U Miocene calc-alkaline volcanics, possibly overlain by Batu Fm limestone with large Lepidocyclina. Suggesting W-dipping subduction zone E of W Sulawesi in E Tertiary continued to E of these islands. Kalao island uplifted coral reefs on andesite. Bonarate, Kalaotoa islands also with uplifted Quaternary reefal limestones)

Guntoro, A. (1999)- The effect of collision of the Banggai-Sula microcontinent to the tectonic development in Central Indonesian region. In: G.H. Teh (ed.) Proc. 9th Reg. Congress Geology, Mineral and Energy Resources of SE Asia (GEOSEA ő98), Kuala Lumpur 1998, Bull. Geol. Soc. Malaysia 43, p. 103-111.
(online at: www.gsm.org.my/products/702001-100829-PDF.pdf)
(Seismic interpretation shows presence of major faults indicating extensional, compressional and inversion tectonics in Makassar Strait, Sulawesi and Bone Bay. Gravity models indicate presence of oceanic crust in middle of Makassar Strait and Bone Bay and remnant subduction to S of Bone Bay. Origin of oceanic crust in Makassar Straits and Bone Bay due to rifting, with E-ward driving mechanism subduction roll-back of Pacific Plate eastward since E Tertiary. Bone Bay openings due to M Miocene collision of Banggai-Sula with Sulawesi, causing displacement and rotation of two Walanae and Palu-Koro faults. Banggai-Sula collisionalso caused inversion structures at E and W sides of N Makassar Basin by inverting Eocene extensional basin)

Guntoro, A. (2004)- The relationship between tectonic development of Central Indonesian region and collision of Banggai-Sula microcontinent to the east Sulawesi. Jurnal Teknologi Mineral (ITB) 11, 1, p.
(Central Indonesia with major faults indicating extension, compression and inversion. Gravity data indicate presence of oceanic crust in middle of Makassar Straits and Bone Bay, related to rifting. Driving mechanism of rifting in Makassar Strait is subduction roll-back of Pacific Plate E-ward since early Tertiary. Rifting in Bone Bay due to collision of Banggai-Sula Microcontinent against Sulawesi causing displacement and rotation of two major faults, Walanae and Palu-Koro)

Guritno, N., D.Q. Coffield & R.A. Cook (1996)- Structural development of central South Sulawesi, Indonesia. Proc. 25th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 253-266.
(S Sulawesi stratigraphy: pre-Tertiary basement, Eocene synrift, Oligo-Miocene post-rift, M Miocene syn-magmatic, and Late Miocene-Pliocene synorogenic sedimentary packages. E part hinterland of exposed Cretaceous basement in W-vergent thrust system. W of basement outcrops is basement-involved, W-vergent Kalosi fold-thrust, with exposed Paleogene sediments. Further W shortening thin-skinned Majene foreland fold-thrust belt. S Sulawesi is W-vergent orogen superimposed on M Miocene magmatic arc. Bone Bay is continent-continent suture recently disrupted by transtensional wrenching and collapse of orogen's eastern extremity. SE Sulawesi E-vergent portion of orogen with allochthonous ophiolite nappes from continent-continent suture. Leading edge of orogen along Banda Sea W margin)

Hadiwijoyo, S., D. Sukarna & K. Sutisna (1993)- Geology of the Pasangkayu Quadrangle, Sulawesi. (Quad. 2014), 1: 250,000, Geol. Res. Dev. Centre (GRDC), Bandung, 19p.
(W Sulawesi map between 1-2°S. Oldest rocks ?Triassic metamorphics (no data to support age), unconformably overlain by low-metamorphic Upper Cretaceous clastics. Overlain by Oligocene and E Miocene Lamasi andesitic-dacitic volcanics. Unconformably overlain by M-L Miocene Talaya andesitic-basaltic series and Late Miocene- Pliocene molasse. Oil seep at Doda. Unlike areas to S, no Eocene rocks present)

Haile, N.S. (1974)- An unusual unconformity of radiolarian chert on schist and gneiss west of Pangkajene, SW arm, Sulawesi (Celebes). Geol. Soc. Malaysia Newsletter 52, p. 21-22.
(Brief note on mid-Cretaceous unconformity in Sungai Dera (tributary of Sg Paring) ~22 km E of Pangkajene, SW Sulawesi. Brecciated gneiss and micaschists of Bantimala Complex are overlain, with horizontal unconformity, by slightly folded ~7m thick red chert sequence. Near base of chert are up to 30cm thick beds of m quartz-mica sandstone with up to 35% lithics of micaschists and altered ultrabasic rocks. (Age of radiolaria in chert Late Albian- E Cenomanian; Wakita 2000))

Haile, N.S. (1978)- Reconnaissance palaeomagnetic results from Sulawesi, Indonesia, and their bearing on palaeogeographic reconstruction. Tectonophysics 46, p. 77-85.
(SW Sulawesi Jurassic radiolarian chert rotated ~35° CCW since Late Mesozoic. E Cretaceous radiolarian chert formed at ~3° and may have formed single plate with Kalimantan and Malay Peninsula, which rotated ~35-50° CCW since Cretaceous. Jurassic cherts from SE Sulawesi formed at high latitude (61°S))

Haile, N.S., A.J. Barber & D.J. Carter (1979)- Mesozoic cherts on crystalline schists in Sulawesi and Timor. J. Geol. Soc. London 136, p. 65-70.
(online at: http://citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.820.2026&rep=rep1&type=pdf)
(Non-metamorphosed Jurassic or Early Cretaceous pelagic radiolarian chert deposited unconformably on brecciated gneiss of Bantimala Complex in Pangkajene valley, SW Sulawesi. Cherts associated with turbiditic lithic sandstones, with grains of mica schist, muscovite, altered ultramafic rock, rare garnet and tourmaline. Radiolaria deemed to be of Jurassic or E Cretaceous age by Ling (no details). Very similar rock succession on Timor (Miomaffo) suggest Sulawesi and Timor probably part of continuous terrain during deposition of radiolarian cherts (see also Harahap 2000))

Hakim, A.Y.A. (2017)- Genesis of orogenic gold in the Latimojong district, South Sulawesi, Indonesia. Dissertation Montanuniversitat Leoben, Germany, p. 1-355.

Hasan, K. (1990)- The Upper Cretaceous flysch succession of the Balangbaru Formation, Southwest Sulawesi, Indonesia. Ph.D. Thesis, University of London, p. 1-336. *(Unpublished)*
(Upper Cretaceous (Turonian-Maastrichtian) Balangbaru Fm ~3300m of deep marine flysch, unconformably over accretionary complex. Not internally deformed, only slight E tilt. Paleocurrent of gravity flows mainly from NW to SE and W to E. Provenance in lower part mainly metamorphic lithics and chert from accretionary complex, upper part influenced by magmatic arc provenance. Tectonic setting small fore-arc basin on trench slope. Basement complex uplifted from significant depth prior to deposition of Balangbaru Fm, thus preventing transport of volcaniclastics into basin)

Hasan, K. (1991)- The Upper Cretaceous flysch succession of the Balangbaru Formation, Southwest Sulawesi. Proc. 20th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, p. 183-208.
(Summary paper of above thesis on *Upper Cretaceous (Turonian-Maastrichtian) Balangbaru Fm 'flysch')*

Hasan, K., R. Garrard & P. Mahodim (1991)- SW Sulawesi, Post-convention field trip guidebook. Indonesian Petroleum Association (IPA), p. 1-61.
(Balangbaru area of SW Sulawesi Albian (111, 115 Ma) age metamorphics. Late Cretaceous (Turonian-Maastrichtian) Balangbaru flysch 3300m thick, unconformably over fractured ultrabasic rocks. Uplift/ erosion event followed by Eocene fluvio-deltaics and Nummulites limestones, overlain by up to 500m Late Eocene- E Miocene Tonasa Limestone)

Hasanusi, D., R. Abimayu, E. Artono & A. Baasir (2004)- Prominent Senoro gas field discovery in Central Sulawesi. In: R.A. Noble et al. (eds.) Proc. Deepwater and Frontier Exploration in Asia & Australia Symposium, Jakarta, Indon. Petroleum Assoc. (IPA), p. 177-197.
(Senoro gas field 1999 discovery in S part of E arm of Sulawesi. Reserves of 3.7 TCF gas and 65 MB condensate. Three play types in Tomori area: Miocene carbonate buildups, wrench-fault anticlines and thrust-

sheet anticlinal structures. Two potential hydrocarbon sources: Jurassic and Miocene marine shales and coals. Geochemical analyses indicate seeps and oils and gas from wells relate to E-M Miocene rocks. Hydrocarbon generation commenced in E-M Pliocene due to Pliocene sedimentation and loading by thrust sheets. Some remigration of hydrocarbons due to regional basin tilting caused by uplifting of fold belt in Pleistocene)

Hasanusi, D., E. Adhitiawan, A. Baasir, L. Lisapaly & R. van Eykenhof (2007)- Seismic inversion as an exciting tool to delineate facies distribution in Tiaka carbonate reservoirs, Sulawesi- Indonesia. Proc. 31st Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA07-G-008, 13p.
(Tiaka field produces oil from E Miocene Tomori limestone, while limited gas bearing zones can be found in M-L Miocene Minahaki limestone. Six oil wells and one dry well drilled. Seismic inversion confirmed dry well was drilled in tight limestone area, while oil wells were drilled in porous limestone area)

Hennig, J., E. Advokaat, A. Rudyawan & R. Hall (2014)- Large sediment accumulations and major subsidence offshore; rapid uplift on land: consequences of extension of Gorontalo Bay and northern Sulawesi. Proc. 38th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA14-G-304, 16p.
(Pliocene rollback of N Sulawesi subduction zone caused subsidence of Gorontalo Bay to water depths of up to 2 km and uplift of Neck and parts of C Sulawesi to 3 km. Late Miocene-Pliocene granitic and volcanic rocks in N Arm and in C Sulawesi all underwent rapid Pliocene exhumation. Neogene metamorphic core complexes in N Arm (Malino) and S of Gorontalo Bay in Tokorondo and Pompangeo Mts and suggest extensional setting. W part of Gorontalo Bay underlain by Australian continental crust added to Sundaland margin in Cretaceous. Metapelite schist and paragneiss from Palu Metamorphic Complex in S Neck of Sulawesi with Cretaceous and Eocene/Oligocene protolith ages and do not represent old Australian basement rocks. Age of deposition of Celebes Molasse at W side of Neck is Pleistocene)

Hennig, J., R. Hall & R.A. Armstrong (2016)- U-Pb zircon geochronology of rocks from west Central Sulawesi, Indonesia: extension-related metamorphism and magmatism during the early stages of mountain building. Gondwana Research 32, p. 41-63.
(online at: http://searg.rhul.ac.uk/pubs/hennig_etal_2016%20Sulawesi%20U-Pb%20zircons.pdf)
(Metamorphic and granitoid rocks from Palu Metamorphic Complex of W C Sulawesi with inherited Proterozoic-Paleogene zircons. Mesoproterozoic and Triassic inherited populations similar to New Guinea Birds Head region (and different from E Java). Some metamorphic rocks with Late Eocene zircons indicating metamorphism not older than Late Eocene, and metamorphosed in Neogene after Sula Spur collision and subsequent extension. Some metapelites of PMC with Cretaceous zircons, possibly from Sundaland (Schwaner

intrusions in Kalimantan). Widespread M Miocene- Pliocene magmatism in W C Sulawesi: (1) M Miocene-Late Miocene (~14-10 Ma?) K-rich shoshonitic suite; (2) Late Miocene-Pliocene shoshonitic to high-K calc-alkaline rocks with intermediate I-type granitoids mainly ~8.5- 5 Ma, felsic S-types ~5- 2.5 Ma. Many rims of metamorphic zircons ~3.8- 3.0 Ma (M Pliocene). Eocene zircons in some metamorphic rocks shows metamorphism of PMC metapelites younger than previously inferred; not Mesozoic or older Australian basement rocks. Co-occurrence of magmatism and metamorphism in M Pliocene during extensional phase)

Hennig, J., R. Hall, M.A. Forster, B.P. Kohn & G.S. Lister (2017)- Rapid cooling and exhumation as a consequence of extension and crustal thinning: implications from the Late Miocene to Pliocene Palu Metamorphic Complex, Sulawesi, Indonesia. Tectonophysics 712-713, p. 600-622.
(online at: http://searg.rhul.ac.uk/pubs/hennig_etal_2017%20Rapid%20cooling%20Palu%20Sulawesi.pdf)
(Metamorphic complexes form 1.5- 2km high mountains in W Sulawesi, and younger than previously thought. Some have Eocene sedimentary protoliths. Palu Metamorphic Complex strongly deformed and partially melted to migmatites. 40Ar/39Ar dating shows cooling in E Pliocene (~5.3-4.8 Ma) in N, and Late Pliocene (~3.1-2.7 Ma) in S. Intruded S-type granites similar Pliocene ages. Fast cooling and rapid exhumation in very young orogenic belt. Contemporaneous magmatism and deformation interpreted as consequence of decompressional melting due to extension. I-type magmatic rocks, separated from PMC by Palu-Koro Fault exhumed from upper crustal levels at moderate rates)

Hennig, J., R. Hall, I. Watkinson & M. Forster (2012)- Timing and mechanisms of exhumation in West Central Sulawesi, Indonesia. AGU Fall Meeting, San Francisco, T43E-2713, 1p. *(Abstract only)*
(online at: http://fallmeeting.agu.org/2012/eposters/eposter/t43e-2713/)
(Basement and intrusive rocks from NW Sulawesi record Neogene deformation, younger than expected, with rapid exhumation. C Sulawesi granitic orthogneiss with zircons with Proterozoic inherited cores and Devonian, Permo-Triassic and Jurassic zircon populations, suggesting Australian-derived terrane. Palu Metamorphic Complex basement rocks complex history of metamorphism. Pre-kinematic cordierite, etc., indicate regional high T-low P metamorphic event. Pliocene cooling age. Granites from Sulawesi Neck and mountain range W of Palu-Koro Fault mainly Late Miocene crystallisation ages (7.2 Ma, 6.4 Ma). Late-stage exhumation started in Neck in Pliocene (2.9 Ma). Magmatism, core complex exhumation and subsidence of Gorontalo Bay all related to crustal thinning due to extension driven by subduction rollback)

Hermanto, B. (2014)- Perkembangan kerangka tektonik Laut Maluku, Kepulauan Banggai-Sula dan lajur ofiolit Sulawesi Timur. J. Geologi Sumberdaya Mineral 15, 2, p. 69-74.

('Biostratigraphy of Middle Tertiary nannofossils in the Tonasa Formation (Rala Section), South Sulawesi'. Nannofossils from lower Tonasa Fm show Late Eocene (NP18-NP20)- Early Oligocene (NP21-NP23) ages. Calciturbidites in Late Eocene (NP20) with larger foraminifera Discocyclina, Pellatispira, etc.. In E Ologocene zone NP23 olistostrome bed with reworked Eocene larger forams)

Kadarusman, A. (2011)- Basement rocks of Sulawesi and their contribution to the metallogenic formation. In: N.I. Basuki (ed.) Proc. Sulawesi Minerals Resources, Manado 2011, Indon. Soc. Econ. Geol. (MGEI) - IAGI, p. 121-130.

(Sulawesi five basement types (1) accretionary-collision complex (Bantimala and Barru Complex in SW arm), (2) metamorphic rocks with continental margin parentage (metamorphic complexes in W, NW, C and SE Sulawesi), (3) ophiolitic rock and oceanic crust (E and N arm, respectively), (4) melange or broken formation (C part), (5) continental granitic basement (Banggai-Sula and Tukang Besi). All basements Mesozoic in age; some metamorphic rocks have Paleozoic protoliths)

Kadarusman, A., H.K. Brueckner, H. Yurimoto, C.D. Parkinson & S. Maruyama (2001)- Geochemistry and Sm-Nd dating of garnet peridotites from Central Sulawesi, and its implication to the Neogene collision complex in Eastern Indonesia. American Geophys. Union (AGU), Fall Meeting 2001, T52D-08, 1p. *(Abstract only)*
(Small garnet-bearing peridotites on Sulawesi in two regions in strike-slip fault zones: Palu-Koro fault zone and right-lateral Ampana fault in Bongka river valley juxtaposed against E Sulawesi ophiolite. P-T time plot suggests prograde subduction zone peridotite. Sm-Nd ages 27-20 Ma. 27 Ma probably peak metamorphism and 20 Ma cooling age. Ultramafic rocks most likely metamorphosed to garnet- assemblages during Late Oligocene- E Miocene continent-continent collision in C Sulawesi. Due to buoyancy peridotites uplifted within Neogene metamorphic complex)

Kadarusman, A., S. Miyashita, S. Maruyama & A. Ishikawa (2002)- The East Sulawesi Ophiolite: the accreted Cretaceous huge ophiolite massif formed by Southwest Pacific superplume. Abstract Superplume Workshop, Tokyo, 4p.
(online at: http://192.129.24.144/licensed_materials/10069/free/conferen/superplu/..)
(Ophiolite complexes of W and C Indonesia (i.e. Java, Kalimantan) of Tethyan provenance, those in E Indonesia probably parts of Circum-Pacific ophiolite belt. E Sulawesi Ophiolite tectonically dismembered, >15 km thick ophiolite sequence from mantle peridotite to mafic cumulate, gabbro, sheeted dolerites and basaltic volcanics. Geochemistry suggests oceanic plateau origin, may have originated in SW Pacific Superplume. Ages Paleogene (60-32 Ma; termination of generation of oceanic lithosphere?) and Cretaceous (79-137 Ma; first generation of oceanic lithosphere?). Obduction onto Sundaland ~30 Ma (age of metamorphic sole))

Kadarusman, A., S. Miyashita, S. Maruyama, C.D. Parkinson & A. Ishikawa (2004)- Petrology, geochemistry and paleogeographic reconstruction of the East Sulawesi ophiolite, Indonesia. Tectonophysics 392, p. 55-83.
(E Sulawesi Ophiolite (ESO) tectonically dismembered and widely distributed in C and E Sulawesi. Comprises, from base: mantle peridotite, gabbro, sheeted dolerites and basaltic volcanic rocks. Possible oceanic plateau origin (15 km thick). Possible Cretaceous origin of oceanic plateau component indicated on basis of calculated paleopositions using plate trajectory analyses together with published paleolatitude data)

Kadarusman, A. & C.D. Parkinson (2000)- Petrology and P-T evolution of garnet peridotites from Central Sulawesi, Indonesia. J. Metamorphic Geol. 18, 2, p. 193-209.
(Alpine-type garnet-bearing peridotites associated with E Cretaceous (140-115 Ma) quartzo-feldspathic gneisses of in two areas of Sulawesi (Palu-Koro fault and outcrops juxtaposed against gabbros and peridotites of E Sulawesi ophiolite in right-lateral Ampana fault). Final exhumation from upper crustal levels facilitated by entrainment in Neogene granitic plutons, and/or Oligocene transtension in deep-seated strike–slip fault zones)

Kadarusman, A., T. van Leeuwen & R. Soeria-Atmadja (2005)- Discovery of eclogite in the Palu region of Central Sulawesi and its implication for the tectonic evolution of Sulawesi. Majalah Geologi Indonesia (IAGI) 20, 2, Spec. Ed., p. 80-89.
(Eclogite and other high-grade metamorphic rocks in float in Palu-Koro fault valley. Proposed history: (1) Early Tertiary conversion of oceanic lithosphere into eclogite after subduction to ~60km below Sundaland; (2) Late Oligocene- Early Miocene collision between microcontinent and Sundaland margin incorporated eclogite fragments into upper plate; (3) latest Miocene- Pliocene rapid uplift after Banggai-Sula collision)

Kadarusman, A., T. van Leeuwen & J. Sopaheluwakan (2011)- Eclogite, peridotite, granulite and associated high-grade rocks from the Palu region, Central Sulawesi, Indonesia: an example of mantle and crust interaction in a young orogenic belt. Proc. Joint 36th HAGI and 40th IAGI Ann. Conv., Makassar, JCM2011-379, 10p.
(Palu region of C Sulawesi part of collision zone with peridotites and high-grade metamorphic rocks (eclogite, granulite). Formed at great depth during collision event between Sundaland and underthrusted Australian

continental fragment sometime in Late Eocene- E Miocene. Radiometric ages of Palu Metamorphic Complex two groups: Mesozoic (144-73 Ma) and Late Miocene-Pliocene (6-2 Ma). Younger ages probably overprint of widespread young granite magmatism)

(Una-Una rocks differ from other volcanoes in Indonesia: K-rich, medium alkaline, transitional between trachytes and andesites. Volcano lies outside orogenic belt, probably at intersection of two basement fissures of NE-SW and SE-NW directions. Extinct volcanism in Togean ridge. Known eruption in 1898, earthquake in 1960 (and major eruption in 1983; Katili & Sudradjat 1984))

Kavalieris, I. (1984)- The geology and geochemistry of the Gunung Pani gold prospect, North Sulawesi. M.Sc. Thesis, Australian National University (ANU), Canberra, p. 1-224 + Appendices
(online at: https://openresearch-repository.anu.edu.au/handle/1885/9263)
(Study of Gunung Pani gold prospect near Marisa village, N Sulawesi, initially surveyed in 1920's. Gold mineralization low grade, large tonnage gold resource, hosted in intrusive porphyritic rhyodacites and pyroclastics of Pliocene- Pleistocene Pani Volcanic Complex. Geochemically Pani Volcanics best compared to rocks from continental margin tectonic settings)

Kavalieris, I., T.M. van Leeuwen & M. Wilson (1992)- Geological setting and styles of mineralisation, North arm of Sulawesi, Indonesia. J. Southeast Asian Earth Sci. 7, p. 113-129.
(Sulawesi N arm Neogene island arc on Paleogene volcanic-sedimentary basement, underlain by oceanic crust. Sulawesi neck metamorphic rocks and felsic granitoids belong to Sundaland continental margin. N Sulawesi Arc two stages, separated by gap 13- 9.5 Ma, reflecting collision of N arm with Sula Platform microcontinent in M Miocene. E Miocene calc-alkaline arc due to W-directed subduction. Arc-continent collision resulted in back-arc thrusting, clockwise rotation of N arm, and inception of subduction along N Sulawesi Trench. Post-collisional magmatism in N Sulawesi Arc produced felsic-mafic volcanic suites related to rifting of former arc rather than subduction. Sulawesi Neck Dondo suite potassic granites of continental affinity. N arm rel. well mineralized. Porphyry Cu-Au mineralization at ~2-4 Ma in oceanic terrane following collision-related arc reversal and Mo mineralization in continental terrane that underwent lower crustal melting during extension following same collision. Cogenetic granites exposed over 5000 km2 and intruded in arcuate belt, more than 400 km long, parallel to Sula Platform collision zone)

('Sulawesi island: structural analysis by remote sensing of large lineaments, an example of collision'. Several major lineaments from W to E: (1) Palu-Koro, 300km, sinistral strike slip zone; (2) Matano and Malili-Kendari, also sinistral; (3) Batui in NE, corresponding partly with ophiolite obduction over Sula islands, continuing offshore as 'Batui thrust'. Small Plio-Pleistocene pull-apart basins over large fault zones. Tectonics linked to NW-SE compression due to convergence of Australian plate and its split-off Sula fragment. Main collision in M Miocene, with obduction of peridotites and continental underthrusting of W side of Sula microcontinent. After that convergence accommodated along major fault zones and absorbed by accretionary prism of N Celebes Trough and Tolo zone at Banda Sea margin. At same time N arm of Sulawesi underwent 90° CW rotation)

Maulana, A. (2009)- Petrology, geochemistry and metamorphic evolution of the South Sulawesi basement rock complexes, Indonesia. M. Phil. Thesis, Australian National University, Canberra, p. 1-188. *(Unpublished)*
(Two pre-Upper Cretaceous basement complexes in SW Sulawesi: (1) Bantimala block: ENE-dipping tectonic slices of metamorphic rocks (eclogites, blueschists, greenschist, some seafloor sediments and volcanics), overlain by ultramafic unit, emplaced from E (records subduction of cold ocean floor and exhumation of deeply subducted material, prior to collision with microcontinents to E and obduction of ultramafics); (2) Barru Block: smaller, 30 km to N, weakly metamorphosed sediments and volcanics, without high-P blueschist and eclogite. Metamorphism at higher geothermal gradients (quartzo-feldspathic gneisses, metabasic amphibolite) at sole of obducted ultramafics. Barru tectonic slices dip to NNW. Barru interpreted as roots of old island arc, subduction of some ocean floor with seamounts, and obduction of different ocean floor material from N. Barru intrusives indicate second arc formed on top of ultramafics as result of renewed subduction)

Maulana, A. (2013)- A petrochemical study of granitic rocks from Sulawesi Island, Indonesia. Doct. Engineering Thesis, Kyushu University, Fukuoka, p. 1-167.
(online at: http://repository.unhas.ac.id/handle/123456789/7116)
(Study of granitic rocks from 11 areas in W and N Sulawesi. Plutons classified as (1) high-K /shoshonitic (HK), mainly in S and CW part of W Sulawesi; (2) high-K calc-alkaline (CAK) in C and NW part of province; (3) low K- tholeiitic, dominant in N Sulawesi. Most granitoids metaluminous I-type granitic rocks. HK and CAK granitic rocks derived from partial melting of lower crustal sources with arc signature; low-K /tholeiitic granites from oceanic crust. Crystallization depths ~4-12 km. Rapid exhumations of granites in W Sulawesi triggered by Late Miocene- Pliocene collision of Banggai- Sula microcontinent with E Sulawesi (Ar-Ar cooling ages 9.5.1 Ma. Exhumation of granites in N Sulawesi attributed to Celebes Sea subduction)

Maulana, A. (2013)- Mineral chemistry of chromite from ultramafic rock in South Sulawesi, Indonesia. J. Penelitian Geosains (Hasanuddin University) 9, 2, p. 83-87.
(online at: http://repository.unhas.ac.id/handle/123456789/15016)
(Chromite occurs in chromitite as podiform lenses or layers 10-40 cm thick in depleted lherzolite and dunite from Bantimala and Barru blocks, S Sulawesi. Also other differences in mineral chemistry, suggesting chromitites originated in different settings, Bantimala from parental melt in island arc environment, Barru from boninitic lava)

Maulana, A., A.G. Christy & D.J. Ellis (2008)- The petrology of eclogites from Bantimala Complex, South Sulawesi, Indonesia. Proc. 37th Ann. Conv. Indon. Assoc. Geol. (IAGI), Bandung, 1, p. 367-398.
(Eclogites tectonic block in E Cretaceous high-Pressure- low T blueschist facies rock of Bantimala basement complex, which consists mainly of high-P Triassic-Jurassic metamorphic rocks and late Albian- Cenomanian and younger sediments and ultramafics. Eclogites range of origins and formed at ~540-615 °C and 18-24 kbar)

Maulana, A., A.G. Christy & D.J. Ellis (2015)- Petrology, geochemistry and tectonic significance of serpentinized ultramafic rocks from the South Arm of Sulawesi, Indonesia. Chemie der Erde 75, 1, p. 73-87.
(Serpentinized ultramafic rocks of S Sulawesi in (1) Bantimala (harzburgite, dunite and clinopyroxenite, with lenses of podiform chromitite) and (2) Barru Block (harzburgite and podiform chromitite). Both derived from supra-subduction zone environment and obducted during closure of small back-arc basins. If no rotation of blocks, Bantimala ultramafics emplaced from ENE, Barru ultramafics from WNW. Ultramafic suites from juxtaposed with metamorphic assemblages and later intruded by younger volcanics. Different metamorphic histories and different directions of obduction, suggest ultramafics of two blocks emplaced in separate events)

Maulana, A., A.G. Christy, D.J. Ellis & M. Brocker (2019)- The distinctive tectonic and metamorphic history of the Barru Block, South Sulawesi, Indonesia: petrological, geochemical and geochronological evidence. J. Asian Earth Sci., p. 170-189.
(online at: https://www.sciencedirect.com/science/article/pii/S1367912018303912?dgcid=author)
(Barru Block in SW Sulawesi composed of tectonic stack of cherts, radiolarian mudstone, breccias, shales, phyllites, mica schist, gneisses, amphibolite and ultramafic rocks. Greenschist- to amphibolite-facies metasedimentary rocks represent detritus from nearby continental blocks redistributed by turbidity currents. Rb-Sr isochrons for mica schists indicate metamorphic ages of ~70.7 ± 2.4 Ma, 107.3 ± 0.7 Ma and 110 ± 2.4 Ma, confirming E Cretaceous (Albian) metamorphism, but also Late Cretaceous (Maastrichtian) metamorphic or deformational event at ~70 Ma. Overall, Barru rocks more felsic than Bantimala. Two blocks accreted at same time (E Cretaceous), but differences in protoliths and metamorphic P-T conditions)

Maulana, A., A.G. Christy, D.J. Ellis, A. Imai & K. Watanabe (2011)- The characteristic of serpentinised ultramafic rocks from South Sulawesi Indonesia: constraint from petrology and geochemistry data. Proc. Int. Symp. on Earth Science and Technology, Fukuoka 2010, p. 301-306.
(online at: http://repository.unhas.ac.id/.)
(Serpentinised ultramafic rocks with different characteristics in two basement complexes in S Sulawesi, Bantimala and Barru blocks)

Maulana, A., A.G. Christy, D.J. Ellis, A. Imai & K. Watanabe (2013)- Geochemistry of eclogite- and blueschist-facies rocks from the Bantimala Complex, South Sulawesi, Indonesia: protolith origin and tectonic setting. Island Arc 22, 4, p. 427-452.
(Bantimala Complex, SW Sulawesi., eclogites both glaucophane-rich and glaucophane-free; blueschists are albite-epidote glaucophanite and quartz-glaucophane schists. Eclogite protoliths include enriched and normal mid-oceanic ridge basalt (E-MORB and N-MORB) and gabbroic cumulates. Blueschists protolithsh include N-MORB, Oceanic Island Basalt (OIB) and Island Arc Basalt (IAB). All protoliths subducted, metamorphosed to blueschist/eclogite-facies and subsequently exhumed. Samples deduced to have come from thicker-crust environments (OIB, IAB) were subducted to shallower depths (blueschist facies) than MORB-derived samples, which reached eclogite-facies conditions.Geochemical data demonstrate variety of ocean floor types subducted under SE margin of Sundaland in Late Jurassic)

Maulana, A., A.G. Christy, D.J. Ellis, Kaharuddin M. & A. Tonggiroh (2009)- Petrology, geochemistry and tectonic significance of the South Sulawesi ultramafic, Indonesia. Proc. 38th Ann. Conv. Indon. Assoc. Geol. (IAGI), Semarang, PITIAGI2009-205, 26p.
(Ultramafic rocks in S Sulawesi Bantimala and Barru basement complexes of different origins. Barru lherzolite derived from supra-subduction zone environment, with no High-P metamorphics. Bantimala ultramafics are cumulates associated with High-P metamorphics (eclogite and blueschist). Stratigraphic position suggests Bantimala ultramafic emplaced onto Bantimala block from spreading of oceanic crust at E-NE part of block. At same time, those from Barru block obducted from back arc basin setting at W-NW part of blocks). Serpentinised

ultramafic rocks suggest different origins of two basement complexes in SW Sulawesi (Bantimala, Barru). Absence of gabbro, pillow basalt, sheeted dykes, etc., suggest incomplete ultramafic suites (dismembered ophiolite sequences). Barru ultramafics emplaced from N, Bantimala from E, suggesting obduction events not caused by W-ward thrust of Australian microcontinent or Pacific oceanic plate on Eurasian margin. Both complexes geochemical differences from ultramafic rocks of East Sulawesi Ophiolite)

Maulana, A., D.J. Ellis & A.G. Christy (2010)- Petrology, geochemistry and tectonic evolution of the South Sulawesi basement rocks, Indonesia. Proc. 34th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA1-G-192, 26p.
(SW Sulawesi two Cretaceous basement outcrop complexes, with different ultramafic rocks and metamorphic histories. Bantimala block (in S) protoliths mainly oceanic basalts. Barru block (in N) quartzo-feldspathic gneisses more felsic and of arc affinity. Bantimala block records subduction of cold ocean floor and exhumation of deeply subducted material. Barru preserve roots of old island arc, subduction of some ocean floor, obduction of different ocean floor material from N, and too warm to preserve blueschist or eclogites. Two blocks derived from different sources and tectonic setting)

Maulana, A., K. Watanabe and K. Yonezu (2016)- Petrology and geochemistry of granitoid from South Sulawesi, Indonesia: implication for Rare Earth Element (REE) occurrences. Int. J. Engineering and Science Applications (UNHAS) 3, 1, p. 79-86.
(online at: http://pasca.unhas.ac.id/ojs/index.php/ijesca/article/view/280/164)
(Late Miocene- Pliocene calk-alkaline I-type granitoids at Polewali and Masamba, 300-400 km N of Makassar, W Sulawesi, with average REE content 249 and 194 ppm. REE-bearing minerals zircon, monazite and apatite)

Maulana, A., K. Watanabe, K. Yonezu, G. Zhang & T. van Leeuwen (2016)- Exhumation and tectono-magmatic process of granitic rock from Sulawesi. Proc. GEOSEA XIV and 45th Ann. Conv. Indon. Assoc. Geologists (IAGI) (GIC 2016), Bandung, p. 362-364.
(In C and N parts of W Sulawesi Late Miocene- Pliocene granite plutons rise to 3000m altitude. P-T data suggest increasing depth of emplacement of plutons from CW to NW Sulawesi (~2.1 to ~11km) and more rapid exhumation (0.37- 2.7 mm/year. Most rapid uplift tied to Palu-Koro fault activity)

Maulana, A., K. Yonezu & K. Watanabe (2014)- Geochemistry of rare earth elements (REE) in the weathered crusts from the granitic rocks in Sulawesi Island, Indonesia. J. Earth Science (China) 25, 3, p. 460-472.
(online at: http://en.earth-science.net/PDF/20140603042501.pdf)
(First study of geochemistry of rare earth elements in weathered crusts of I-type and calc-alkaline to high-K (shoshonitic) granites at Mamasa and Palu region, NW Sulawesi)

Maulana, J.P. (2011)- Source indication of oil seep from Paniki River, Kalukku, Mamuju, West Sulawesi based on geochemical characterization. Proc. Joint. 36th HAGI and 40th IAGI Ann. Conv., Makassar, JCM2011-030, 10p.

(Paniki River oil seep near Amberaro Village, 40km NE of Mamuju, SW Sulawesi, with oil that underwent heavy biodegradation. Common presence of bicadinane, oleanoids, oleanane, and taraxastane show oil probably derived from terrestrial higher plant source, probably from Eocene coals or carbonaceous clays)

Mawaleda, M., E. Suparka, C.I. Abdullah, N.I. Basuki, M. Forster, Jamal & Kaharuddin (2017)- Hydrothermal alteration and timing of gold mineralisation in the Rumbia Complex, Southeast Arm of Sulawesi, Indonesia. In: 2nd Int. Conf. Transdisciplinary research on environmental problems in Southeast Asia (TREPSEA), Bandung 2016, IOP Conf. Series, Earth Environm. Science, 71, 012030, p. 1-15.
(online at: http://iopscience.iop.org/article/10.1088/1755-1315/71/1/012030/pdf)
(Rumbia WNW-ESE trending high P-low T metamorphic schist complex of SE Sulawesi (mainly mica schist, some blueschist) with gold mineralization in two phases: (1) initial phase related to deformation and exhumation of HP metamorphic rocks (gold, silver, stibnite, chalcopyrite, galena, etc.; syn-tectonic, ~23 Ma; mainly in N and NW parts of Rumbia Complex); (2) hydrothermal mineralization associated with extensional phase at between ~15-7 Ma. Two possible tectonic scenarios(see also Musri et al. 2016)

Mayall, M.J. & M. Cox (1988)- Deposition and diagenesis of Miocene limestones, Sengkang Basin, Sulawesi, Indonesia. Sedimentary Geology 59, p. 77-92.
(Porosity evolution of Late Miocene knoll-reef carbonates of Kampung Baru gas field, SW Sulawesi)

McCaffrey, R., E.A. Silver & R.W. Raitt (1981)- Seismic refraction studies in the East Arm, Sulawesi- Banggai Islands region of Eastern Indonesia. In: A.J. Barber & S. Wiryosujono (eds.) The geology and tectonics of Eastern Indonesia, Proc. CCOP-IOC SEATAR Working Group Mtg., Bandung 1979, Geol. Res. Dev. Centre (GRDC), Bandung, Spec. Publ. 2, p. 321-325.
(online at: http://web.pdx.edu/~mccaf/pubs/mccaffrey_sulawesi_grdc_1981.pdf)
(Two seismic refraction lines in E Gorontalo basin and E of E arm of Sulawesi (lines not shown). Show block faulted basement stepping down in Gorontalo Basin oceanic lithosphere)

McCaffrey, R. & R. Sutardjo (1982)- Reconnaissance microearthquake survey of Sulawesi, Indonesia. Geophysical Research Letters 9, 8, p. 793-796.
Zone of microearthquakes dipping to N from Batui Thrust zone suggests leading edge of Banggai Island block was subducted to at least 100 km depth. E Gorontalo Basin earthquake zone may connect with deep seismic zone under Celebes Sea Basin. Beneath W Gorontalo Basin narrow zone of earthquakes dips S, probably within lithosphere of Celebes Sea Basin subducted at N Sulawesi Trench. Shallow earthquakes near Lake Matano in C Sulawesi, possibly on Matano Fault, suggest E-W extension)

McCaffrey, R., R. Sutardjo, R. Susanto, R. Buyung, B. Sukarman et al. (1983)- Micro-earthquake survey of the Molucca Sea and Sulawesi, Indonesia. Bull. Geol. Res. Dev. Centre 7, p. 13-23.
(Several hundred, mostly shallow, microearthquakes recorded below Molucca Sea and Tomini Gulf/Gorontalo)

Meeren, J. (2009)- A geothermobarometric study on garnet peridotite and granulite from the Palu region, Central Sulawesi, Indonesia. M.Sc. Thesis, University of Utrecht, p. 1-101. *(Unpublished)*

Meeren, J. & H.L.M. van Roermund (2009)- A two stage exhumation model for HP rocks from the Palu Region, Central Sulawesi, Indonesia- a geothermobarometric study. In: 8th Int. Eclogite Conference (IEC), Xining, China 2008, 2p. *(Abstract only)*
(Garnet peridotite and granulite thin tectonic slices (< 10m) in Palu-Koro Fault zone, crosscutting Cretaceous Palu Metamorphic Complex. Palu garnet peridotite peak metamorphic conditions of ~1030°C/18 kbar and ~855 °C/ 10 2 kbar for retrograde assemblage. Palu granulite peak metamorphic conditions of ~655 °C/ 19 kbar. Palu granulite (microcontinental fragment) subducted in Cretaceous subduction system at Sundaland margin. After exhumation from 65 km to lower crustal levels, granulite stored in lower crust until Miocene upwelling asthenosphere invaded subcontinental lithosphere and caused heating in lower crust under C

Sulawesi. Palu garnet peridotite started ascent to lower crustal levels from ~65 km in E Miocene. Final exhumation of Palu HP rock facilitated by transpression along Palu-Koro fault. Occurrence of HP rock in C Indonesia cannot be explained by simple collision event in subduction system of Cretaceous age)

Mesdag, F.T. (1914)- De goudmijn "Totok" te Totok, Noord-Celebes. Verhandelingen Geologisch-Mijnbouwkundig Genootschap Nederland Kol., Mijnbouwkundig Ser. 1, p. 191-203.

(Bakan gold mine 200km SW of Manado in N Arm of Sulawesi operational since 2013. Cluster of epithermal high-sulphidation gold occurrences hosted by Plio-Pleistocene dacitic tuffs that are unconformable over Mioccene andesitic lavas and sandstones. Mineralization similar to North Lanut mine)

Parkinson, C.D. (1991)- The petrology, structure and geologic history of the metamorphic rocks of Central Sulawesi, Indonesia. Ph.D. Thesis, University of London, p. 1-337. *(Unpublished)*
(Includes description of metamorphic sole below obducted E Sulawesi ophiolite in C Sulawesi)

Parkinson, C.D. (1991)- Counterclockwise P-T-t paths from Sulawesi meta-basites: implications for subduction zone metamorphism. In: Proc. Symposium on the dynamics of subduction and its products, Res. Dev. Centre Geotechnology, Indonesian Inst. Science (LIPI), p. 225-226.

Parkinson, C.D. (1996)- The origin and significance of metamorphosed tectonic blocks in melanges: evidence from Sulawesi, Indonesia. Terra Nova 8, p. 312-323.
(Block-bearing melange ('knockers' in sheared mudstone) of C Sulawesi Peleru Melange Complex overlain by E Sulawesi ophiolite nappe, with Mowomba metamorphic sole sequence at base (formed at E-dipping subduction zone). Most blocks are ophiolite, also blueschist, etc. Matrix serpentinite and red phyllite. Direct genetic relationship between high-grade tectonic blocks in melange and amphibolites in metamorphic sole. High-grade tectonic blocks originated in thin, thermally zoned metamorphic sheet welded to oceanic hanging wall plate at inception of subduction. Break-up at depth by tectonic erosion led to dispersal of fragments into newly developed serpentinite melange wedge)

Parkinson C. (1998)- An outline of the petrology, structure and age of the Pompangeo Schist Complex of Central Sulawesi, Indonesia. The Island Arc 7, 1-2, p. 231-245.
(C Sulawesi Pompangeo Schist is metamorphosed accretionary complex, with phyllitic marble, phyllite, schist and quartzite, all of terrigenous- marine origin. Along E margin schists interthrust with unmetamorphosed Early Jurassic sandstone (may be Cretaceous?; JTvG), which may be parent material. Schists unconformably overlain by Albian-Cenomanian pelagic sediment. Synmetamorphic NNW-SSE striking and W dipping isoclinal folding. E-W metamorphic gradient, representing rel. low T gradient of 15°C/ km. K-Ar ages ~108-114 Ma. Correlative metamorphic rocks may underlie W Sulawesi Neogene magmatic province. Pompangeo and Bantimala schists probably generated in same subduction system responsible for C Kalimantan Mesozoic arc)

Parkinson, C.D. (1998)- Emplacement of the East Sulawesi ophiolite: evidence from sub-ophiolite metamorphic rocks. J. Southeast Asian Earth Sci. 16, 1, p. 13-28.
(Metamorphic sole at base E Sulawesi ophiolite composed of thin garnet and epidote amphibolite and basal greenschist metaclastics, with K/Ar ages ~30 Ma (= cooling age?). E-dipping tectonite fabrics in amphibolite and underlying basement mica schist and overlying peridotite indicate orthogonal E to W emplacement of ophiolite in C Sulawesi. Followed by W Sulawesi arc volcanism in E Miocene and collision of Banggai-Sula Platform in Late Miocene)

Parkinson, C.D. & T. Dooley (1996)- Basin formation and strain partitioning along strike-slip fault zones. Bull. Geol. Survey Japan 47, 8, p. 427-436.
(online at: https://www.gsj.jp/data/bull-gsj/47-08_02.pdf)
(On strike-slip fault zones, with example of Sulawesi: series of curvilinear sinistral strike-slip fault zones (Palo-Kuro, Poso, Matano and Lawanopo), formed after Late Miocene collision of Sula Platform and E Sulawesi Ophiolite)

Parkinson, C.D. & I. Katayama (1999)- Present-day ultrahigh-pressure conditions of coesite inclusions in zircon and garnet: evidence from laser Raman microspectroscopy. Geology 27, p. 979-982.
(Coesite is high-pressure polymorph of quartz and occurs as inclusions in deeply subducted, metamorphosed crustal rocks in several Eurasian collisional orogens, including in zircons in eclogites from Bantimala Complex, S Sulawesi. It is primary indicator mineral of ultrahigh-pressure metamorphism)

Parkinson, C.D. & I. Katayama (1999)- Metamorphic microdiamond and coesite from Sulawesi, Indonesia; evidence of deep subduction at the SE Sundaland margin. American Geoph. Union (AGU), 1999 Fall Mtg., EOS Transactions 80, 46, Suppl., p. 1181. *(Abstract only)*
(In situ diamond grains identified by laser Raman spectroscopy within quartz pseudomorphs after coesite in E Cretaceous (130-120 Ma) garnet in jadeite quartzite of Bantimala complex, C Sulawesi. Indicate ultrahigh-pressure conditions (>4 GPa) and subduction of continental crust to depths within diamond stability field, followed by rapid exhumation)

Parkinson, C.D., K. Miyazaki, K. Wakita, A.J. Barber & D.A. Carswell (1998)- An overview and tectonic synthesis of the Pre-Tertiary very-high pressure metamorphic and associated rocks of Java, Sulawesi and Kalimantan, Indonesia. Island Arc 7, p. 184-200.
(High-P metamorphics common in Cretaceous accretionary complexes of Java, Sulawesi, SE Kalimantan. Many occur as imbricate slices of carbonate, quartzose and pelitic schists, interthrust with subordinate basic schists and serpentinite. They are mainly low-intermediate metamorphic grade, with K-Ar ages of 110-120 Ma. Metamorphic rocks from depths >60 km sporadically exposed, usually as tectonic blocks. Many metamorphics probably recrystallized in N-dipping subduction zone at Sundaland craton margin in E Cretaceous. Exhumation possibly facilitated by collision of Gondwanan continental fragment with Sundaland margin at ~120-115 Ma)

Patria, A., A.H. Dewangga, R.S. Putranto & B. Priadi (2012)- Geochemistry of igneous rocks from Bintauna area, North Sulawesi: tectonic implication. Proc. 41st Ann. Conv. Indon. Assoc. Geol. (IAGI), Yogyakarta, 2012-GD-11, 4p.
(Tinombo Fm, Wobudu Breccias and Dolokapa Fm outcrop in Bintauna-Labuanaki areas, N coast of Sulawesi N Arm. Samples ages ranging of 41.8- 13.9 Ma. Geochemistry indicates volcanics are Low-K volcanic arc basalts, related to Late Eocene- M Miocene subduction. No maps)

Pearson, D.F. & N.M. Caira (1999)- The geology and metallogeny of central North Sulawesi. In: G. Weber (ed.) Proc. PACRIM ô99 Congress, Australasian Inst. of Mining and Metallurgy (AusIMM), Parkville, 4/99, p. 311-326.
(N Arm Sulawesi gold and base metal mineralisation styles: porphyry Cu-Au; porphyry-related gold and base metal veins; high-sulphidation Cu-Au-As; low-sulphidation epithermal Au; hydrothermal breccias; and sediment-hosted Au mineralisation. Different Miocene and Pliocene porphyry systems recognised whilst most remaining epithermal mineralisation Pliocene or later. Central N Arm of Sulawesi Miocene magmatic island arc on E Tertiary oceanic basaltic basement, overprinted by Pliocene arc. Structural fabric dominated by SSE arc-normal and ESE arc-parallel faults, established during Miocene under dextral wrench regime. Intersections of major fault sets favoured sites for Miocene porphyry Cu-Au)

Perdana, M.J. & H. Amijaya (2010)- Identification of geochemical degradation of oil seep from Paniki River, Kalukku, Mamuju, West Sulawesi. Proc. 34th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA10-SG-036, 10p.
(Oil seeps in Paniki River, Kalukku, 40 km NE of Mamuju, W. Sulawesi, considered to have originated from Eocene coals or carbonaceous clays of Toraja Fm. GCMS work suggests severe biodegradation)

Perdana, M.J. & H. Amijaya (2011)- Source indication of oil seep from Paniki River, Kalukku, Mamuju, West Sulawesi, based on geochemical characterization. Proc. 36th HAGI and 40th IAGI Ann. Conv., Makassar, JCM2011-030, 10p.
(Many oil and gas seeps in W Sulawesi area. Paniki River seep oil biodegraded. Common bicadinane, oleanoids, oleanane, and taraxastane show oil probably derived from higher land plants. No gammaceranes)

Perello, J.A. (1994)- Geology, porphyry Cu-Au, and epithermal Cu-Au-Ag mineralization of the Tombulilato district, North Sulawesi, Indonesia. J. Geochemical Exploration 50, p. 221-256.
(N Sulawesi Tombulilato district island arc-type volcano-sedimentary pile with >3400m of Late Miocene(?) - Pleistocene volcanics, interbedded with marine and continental sediments. Sequence intruded by high-level stocks and dikes, cut by Late Pliocene- Pleistocene diatreme breccias, some associated with Cu mineralization. Main compressive deformation event in Pliocene. Mineralization between 2.9 - 0.9 Ma as part of district-scale hydrothermal system. Uplift and erosion removed ~2 km of rock in last 3 Myr)

Priadi, B., H. Bellon, R.C. Maury, M. Polve, R. Soeria-Atmadja & J.C. Philippet (1994)- Magmatic evolution in Sulawesi in the light of new 40K-40Ar age data. Proc. 23rd Ann. Conv. Indon. Assoc. Geol. (IAGI), Jakarta, 1, p. 355-369.
(W Sulawesi volcanic episodes: Jurassic (~150 Ma) back arc basin magmatism, Paleocene subduction-related magmatism (~60 Ma), Oligocene- M Miocene (40-~15 Ma; well-developed in N Sulawesi; also in W and C Sulawesi) subduction-related magmatism and Miocene-Recent (~13-0 Ma) collision-related magmatism)

Priadi, B., R.C. Maury, R. Soeria-Atmadja, M. Polve & H. Bellon (1991)- Tertiary and Quaternary magmatism in Central Sulawesi: chronological and petrological constraints. In: Proc. Silver Jubilee Convention Dynamics of subduction and its products, Yogyakarta 1991, LIPI, p. 171-194.
(same title as Priadi et al. 1994)

Priadi, B., M. Polve, R.C. Maury, R. Soeria-Atmadja & H. Bellon (1993)- Geodynamic implications of Neogene potassic calc-alkaline magmatism in Central of Sulawesi: geochemical and isotopic constraints. Proc. 22nd Ann. Conv. Indon. Assoc. Geol. (IAGI), Bandung, 1, p. 59-81.
(Potassic calc-alkaline magmatism of C Sulawesi mostly acidic, ranging in age fom 6.5 Ma- Recent. Isotopic character similar to Australian blocks, suggesting result of collision between two 'Australian' blocks, Banggai

Sula in E and western block that is either microcontinent of Australian origin or ancient volcanic arc that incorporated large volume of sediment)

Priadi, B., M. Polve, R.C. Maury, H. Bellon, R. Soeria-Atmadja, J.L. Joron & J. Cotten (1994)- Tertiary and Quaternary magmatism in Central Sulawesi: chronological and petrological constraints. J. Southeast Asian Earth Sci. 9, p. 81-93.
(Four main magmatic events in C Sulawesi: (1) Late Eocene and Oligocene island arc tholeiites and calc-alkaline intrusions. (2) Lamasi Volcanics: 33-15 My K-Ar ages, but may not be magmatic ages. MORB-type affinity and anomalies indicative of BABB affinity. Origin still enigmatic. (3) Important shoshonitic affinity event at 10.1-11.9 Ma, probably post-subduction associations emplaced in S Sulawesi in Late Miocene and might derive from melting of mantle material after mantle metasomatised during former episode of subduction. (4) Last event 6.5- 0.6 Ma granitic rocks, rhyolites and widely distributed rhyolitic Barupu tuff pyroclastics (0.6 Ma). All magmatic rocks K-rich calc-alkaline composition, lacking basaltic and intermediate magmas (SiO2 >60%) and high enrichments in incompatible elements and radiogenic Sr isotopic signature. This is consistent with strong crustal imprint by melting of underthrusted continental crust in collisional context)

Priadi, B., R. Soeria-Atmadja, R. Maury, H. Bellon & M. Polve (1997)- The occurrence of back-arc magmatism in Sulawesi: geochemical constraints on geodynamic reconstruction. Proc. 26th Ann. Conv. Indon. Assoc. Geol. (IAGI), Jakarta, p. 390-403.
(Two volcanic units along E edge of S arm of Sulawesi: (1) Kalamiseng Fm pillow lava-breccia, with Miocene (~17-22 Ma K-Ar ages), but may be older; (2) Lamasi Volcanics in NE part of S Sulawesi K-Ar ages suggest 3 episodes of activity, including oldest ages of Sulawesi volcanics: (1) 'Palopo ophiolite' 'back-arc' micro-gabbro cut by dikes; Late Jurassic-earliest Cretaceous (~159-137 Ma) and subduction-related (2) Oligocene Lamasi-Songka volcanics (~33-28 Ma) and (3) M Miocene Lamasi- Pohi Volcanics (~15.4 Ma) volcanics. In N part of W Sulawesi and N Sulawesi mainly Eocene (~34-50 Ma) Tinombo Fm mostly back arc basin chemistry and Paleogene K-Ar ages. Younger volcanics less common and subduction related)

('Eocene- Lower Miocene gravity sedimentation in Tana Toraja, South Sulawesi (Indonesia)')

Sasajima, S., S. Nishimura, K. Hirooka, Y. Otofuji, T. Van Leeuwen & F. Hehuwat (1978)- Paleomagnetic results and fission track ages obtained from the Western and Northern Sulawesi, East Indonesia. In: M. Kono (ed.) Rock magnetism and paleogeophysics, Tokyo, 5, p. 73-80.
(online at:
http://peach.center.ous.ac.jp/rprep/Rock%20Magnetism%20and%20Paleogeophysics%20vol5%201978.pdf)
(Reconnaissance paleomagnetic work combined with fission track age dating of U Cretaceous- Pliocene rocks mainly from Biru area, E of Makassar, SW Sulawesi. M Miocene and younger rocks similar position as present-

day. Probable 45° CCW rotation beween 63-13 Ma (authors suggest probably between 19-13 Ma, but no explanation why; JTvG), possibly in tandem with Malay Peninsula and W Borneo from which Haile (1978) reported similar 35-50° CCW rotations)

Sasajima, S., S. Nishimura, K. Hirooka, Y. Otofuji, T. Van Leeuwen & F. Hehuwat (1980)- Paleomagnetic reconnaissance from Northern arm of Sulawesi, Indonesia. In: S. Nishimura (ed.) Physical geology of Indonesian Island arcs, Kyoto University, p. 23-34.

Sasajima, S., S. Nishimura, K. Hirooka & Y Otofuji (1981)- Paleomagnetic studies combined with fission-track datings on the western arc of Sulawesi, east Indonesia. In: A.J. Barber & S. Wiryosujono (eds.)The geology and tectonics of Eastern Indonesia, Proc. CCOP-IOC SEATAR Working Group Mtg., Bandung 1979, Geol. Res. Dev. Centre (GRDC), Bandung, Spec. Publ. 2, p. 305-311.
(Same as Sasajima et al. (1980). SW arm of Sulawesi 40° CCW rotation since Paleocene- E Miocene)

Sasajima, S., T. Van Leeuwen, F. Hehuwat, S. Nishimura, K. Hirooka & Y. Otofuji (1980)- Paleomagnetic studies combined with fission-track datings on the Western Arm of Sulawesi, East Indonesia. Tectonophysics 64, p. 163-172.
(Paleogene- E Miocene paleomagnetic pole for SW Sulawesi very different from that in M Miocene- Recent. This suggests possibly 19-13 Ma major tectonic event caused ~40-45° of CCW rotation. Postulated collision followed by welding of E and W Sulawesi in Pliocene (Katili, 1978) may be cause. Our data does not support hypothesis that W Sulawesi derived from dispersal of Gondwanaland)

Satyana, A.H. (2006)- Docking and post-docking tectonic escapes of Eastern Sulawesi: collisional convergence and their implications to petroleum habitat. Proc. Jakarta 2006 Int. Geosc. Conf., Indon. Petroleum Assoc. (IPA), PG-16, 4p. *(Extended Abstract only)*
(Summary of Sulawesi tectonic history of docking of microcontinents (Buton at 11 Ma, Sula at 5 Ma), followed by escape towards free edges, creating arc-polarity reversal, large strike slip faults, local extension, etc.)

Satyana, A.H. (2011)- Sulawesi: where two worlds collided- geologic controls on biogeographic Wallace's Line. Proc. Joint 36th HAGI and 40th IAGI Ann. Conv., Makassar, JCM2011-065, 16p.
(On Cenozoic geological history controlling present-day Wallace's Line, which separates Asian and Australian fauna and flora. Sulawesi island shows mixture of Oriental and Australasian faunas)

Satyana, A.H., S. Damayanti & C. Armandita (2012)- Tectonics, stratigraphy and geochemistry of the Makassar Straits: recent updates of exploring West Sulawesi offshore, opportunities and risks, Proc. 36th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA12-G-156, p. 1-21.
(W part of Makassar Straits prolific petroleum province, sourced and reservoired by Miocene-Pliocene Mahakam deltaic sediments. E part of Makassar Straits very different. Makassar Straits extension began in M Eocene and formed graben/ half-graben above which is important unconformity of probable Late Eocene age, marking top of synrift sequence. Nature of basement still debated in areas. Onshore W Sulawesi seeps and offshore microseeps suggest terrestrial M-L Eocene coals and coaly shales are main source rocks)

Satyana, A.H., T. Faulin & S.N. Mulyati (2011)- Tectonic evolution of Sulawesi area: implications for proven and prospective petroleum plays. Proc. Joint 36th HAGI and 40th IAGI Ann. Conv., Makassar, JCM2011-064, 30p.
(Substantial review of Cenozoic tectonic evolution, basins and hydrocarbons of Sulawesi. Sulawesi formed by collision between drifted part of SE Sundaland and drifted microcontinents of Indian-Australian Plate. The collision took place during Oligocene-early Pliocene)

Satyana, A.H. & M.E.M. Purwaningsih (2011)- Collision of microcontinents with Eastern Sulawesi: records from uplifted reef terraces and proven-potential petroleum plays. Proc. 35th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA11-G-219, 25p.
(Sulawesi is assemblage of collided terranes. Buton-Tukang Besi micro-continent collided with SE Sulawesi/ Muna Block from E Miocene- Late Miocene. Collision overthrusted Kapantoreh ophiolitic suture (here

interpreted as oceanic crust originally located between Muna and Buton), shortened and uplifted Buton. Tukang Besi single microcontinent with Buton, and separated from Buton as response to post-collisional tectonics. Banggai-Sula microcontinent collided with Sulawesi E Arm in M Miocene- E Pliocene. Post-collisional uplifts exhumed micro-continents in Buton, Wakatobi (Tukang Besi), and Luwuk (Banggai) areas and uplift of Quaternary reef terraces)

Satyana, A.H. & S. Zaitun (2016)- Origin of oils and gases at Banggai-Sula microcontinent, Eastern Sulawesi-North Moluccas: constraints from biomarkers and isotope geochemistry- implications for further exploration of Cenozoic and Pre-Cenozoic objectives. Proc. 40th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA16-575-G, 27p.
(Oils in Banggai Basin oil-gas fields (Tiaka, Senoro, Minahaki, etc.) and onshore seeps (Kolo, Dayuk, Toikli, etc.) with common oleanane and relatively high sulfur sourced from marine E Miocene Tomori Fm carbonates-shaly carbonates (type A oils) and M Miocene Matindok shales- calcareous shales (type B oils). No evidence of petroleum contribution from Jurassic- Cretaceous rocks in Banggai Basin, although gas seeps on Sula islands tied to Pre-Cenozoic source rocks in graben areas of offshore Taliabu-Mangole Shelf)

Schepmann, M.M. (1907)- Mollusken aus posttertiaren Schichten von Celebes. Sammlungen Geol. Reichs-Museums Leiden, Ser. 1, 8, E.J. Brill, p. 153-203.
(online at: http://repository.naturalis.nl/document/552420)
('Molluscs from the post-Tertiary beds of Sulawesi'. Descriptions of molluscs from Kajoe ragi, Manado area, N Sulawesi, collected by Fennema. Mainly gastropods (15 species of Conus, 7 species of Pleurotoma, 10 species of Drillia, 6 species of Mitra, 19 species of Turricula, 11 species of Nassa, 13 speies of Cypraea, etc. spp.) and some pelecypods (Venus, Spondylus, Chlamys, etc.)

('Petrology and geochemistry of volcanic rocks in Togean Islands, Tomini Bay, Central Sulawesi: implications for the tectonic structure of Sulawesi'. Volcanic rocks from Togean Islands 3 types:(1) Una-Una (adakitic subduction volcanics from partial melting of Celebes Sea slab at 70-85 km depth), (2) Togean (both adakites, basaltic-trachyandesite and result of partial melting of Sulawesi Sea slab in amphibole-eclogite zone) and (3) Walea (tholeitic basaltic-andesite and tholeite basalt, interpreted as upper part of ophiolite, formed around 6 Ma from seafloor spreading due to rollback of oceanic crust of Banggai-Sula microcontinent)

Sendjaja, P. & I.G.B.E. Sucipta (2008)- Adakite rock From Una-Una island, Central Sulawesi. Proc. 37th Ann. Conv. Indon. Assoc. Geol. (IAGI), Bandung, 1, p. 212-228.
(Pyroclastics and lavas from Una-Una Island in Tomini Gulf adakitic geochemical signature: SiO2 >60%, MgO <3%, low Y and HREE relative to normal island arc volcanics, high Sr and Nb enrichment. Tectonically, adakites formed by partial melting of young oceanic crust. Crust presently subducted at nearby trench may be <25 Ma old)

Sendjaja, P., E. Suparka, C.I. Abdullah, E. Sucipta & T. Hasenaka (2011)- A petrology and geochemistry of the volcanic rocks from the Togean Islands, Central Sulawesi, Indonesia: estimation of subduction component at a complex tectonic regime. Proc. Joint. 36th HAGI and 40th IAGI Ann. Conv., Makassar, JCM2011-166, 13p.
(Togean Island in Tomini Gulf. Nearby Una-Una volcano typical adakitic rocks. Mio-Pliocene volcanics of Togean islands further toE quite different. Volcanic rocks from Walea Kodi and Walea Bahi Islands lower SiO2 and low Sr content than Una-Una. Compositions seems similar to volcanic rocks from Sangihe Region)

Setiawan, I., S. Indarto, A.F. Ismayanto & Sudarsono (2012)- Karakter dan tipe mineralisasi hidrotermal di wilayah Bombana berdasarkan studi mineralogi dan geokimia. J. Sumber Daya Geologi 22, 3, p. 155-168.
(online at: http://jgsm.geologi.esdm.go.id/index.php/JGSM/article/view/115/107)
('Character and the type of hydrothermal mineralization in the Bombana area based on a study of mineralogy and geochemistry'. Bombana gold mineralization in metamorphic rocks of Rumbia Mts, with no obvious connection with magmatism. Area with metamorphic and ultramafic rocks (garnet- glaukophane- amphibole schist, peridotite, serpentinite, metasediments, etc.). Gold mineralization of epithermal-mesothermal type, resulting from hydrothermal processes, formed after metamorphism. Ore minerals gold, pyrite, chalcopyrite, goethite, lepidocrocite and cinnabar, commonly associated with quartz veins/ K-Ar age of plagioclase of meta-andesite 85± 2 Ma)

Setiawan, N.I., Y. Osanai, N. Nakano & T. Adachi (2014)- Metamorphic evolution of garnet-biotite-muscovite schist from Barru Complex in South Sulawesi, Indonesia. J. Southeast Asian Applied Geol. (UGM) 6, 2, p. 68-78.
(online at: http://jurnal.ugm.ac.id/jag/article/download/7219/5658)
(Mid-Cretaceous garnet-biotite-muscovite schist from Dengedenge River in Barru Complex, 30 km N of Bantimala, SW Sulawesi. Bordered in N by ultramafic rocks and in S by Late Cretaceous turbidites. Foliation of schist varies from N80°E to N30°E, dipping 30-60° to E (SE). Garnet, biotite, muscovite, quartz, rutile and plagioclase represent peak P-T condition of this rock, estimated at T= 501-562ºC and P= 0.89-0.97 GPa. Within geothermal gradient P-T path of eclogite from Bantimala Complex. Wakita 1994 K-Ar age ~106 Ma)

Setiawan, N.I., Y. Osanai, N. Nakano & T. Adachi (2013)- Jadeite jade from South Sulawesi in Indonesia and its geological significance. In: N.I. Setiawan et al. (eds.) Proc. Int. Conf. Geological Engineering, Gadjah Mada University, Yogyakarta 2013, ER05, p. 40-56.
(online at: http://lib.ugm.ac.id/digitasi/upload/4244_jhon-mu.140108-nugroho.pdf)
(Jadeite abundant in high-P garnet-jadeite-quartz metamorphic rock in E Cretaceous Bantimala subduction compex of S Sulawesi. Rock mainly jadeite, garnet, quartz, phengite, epidote, with minor glaucophane and rutile. Rock experienced peak P-T condition at 2.2-2.5 GPa and 500-540 ºC and subsequently retrogressed)

Setiawan, N.I., Y. Osanai, N. Nakano, T. Adachi, K. Yonemura, A. Yoshimoto (2016)- Prograde and retrograde evolution of eclogites from the Bantimala Complex in South Sulawesi, Indonesia. J. Mineralogical Petrological Sci. 111, 3, p. 211-225.
(online at: https://www.jstage.jst.go.jp/article/jmps/111/3/111_150907/_pdf)
(Evolution of high-P metamorphic rocks from Bantimala Complex, S Sulawesi. Early Cretaceous K-Ar ages of 113-136 Ma probably reflect time of exhumation cooling. Eclogites and glaucophane occur as tectonic blocks in sheared serpentinites. Garnet rims in eclogite formed at peak P-T conditions of 2.3-2.7 GPa and 615-680 °C . Very low geothermal gradient during prograde path suggests subduction of old and cold oceanic crust)

Setiawan, N.I., Y. Osanai, N. Nakano, T. Adachi, K. Yonemura, A. Yoshimoto, L.D. Setiadji, K. Mamma & J. Wahyudiono (2013)- Geochemical characteristics of metamorphic rocks from South Sulawesi, Central Java, and South and West Kalimantan in Indonesia. Proc. 5th AUNS/SEED-Net Regional Conf. 'Geomagnetic signals in the Sengkang Basin and its implications for structural and basement configuration'. Intensity of magnetic anomalies at Sengkang Basin from -750- 400 nT. Sengkang Basin underlain by high magnetic ultrabasic rocks (especially E flank?). Geologic structures NE-SW fold, cut by NW-SE fault)

Setyoko, J., S. Hadipandoyo & S. Oemar (2000)- Hydrocarbon resources assessment of the Late Miocene Tacipi Formation in the Bone Basin, South Sulawesi, Indonesia. Proc. 36th Sess. Coord. Comm. Coastal and Offshore Programmes E and SE Asia (CCOP), Hanoi 1999, p. 35-49.
(Late Miocene Tacipi Fm reefal limestone gas producing in Kampung Baru Field, E Sengkang sub-basin of Bone Basin. Porosity generally 20-30% (moldic, vugular and fracture). Source rocks Eocene and Oligocene carbonaceous sediments. Unproven potential plays in Eocene Toraja Fm sst, Oligocene Toraja Fm carbonate and Pliocene Walanae Fm sst. Undiscovered resources in Tacipi play in Bone basin assessed as maximum 22.5 Gm3 and 5.3 million Tons of oil)

Shaban, G., F. Fadlin & B. Priadi (2016)- Geochemical signatures of potassic to sodic Adang Volcanics, Western Sulawesi: implications for their tectonic setting and origin. Indonesian J. Geoscience 3, 3, p. 197-216.
(online at: https://ijog.geologi.esdm.go.id/index.php/IJOG/article/view/344/226)
(Adang Volcanics ~400m thick series of (ultra-) potassic- sodic lavas and tuffs of mainly trachytic composition, part of widespread Late Cenozoic (latest Miocene- E Pliocene) high-K volcanics in W Sulawesi. Tectonic setting and origin debated. Major rock forming minerals leucite, diopside/aegirine and high T phlogopite. Geochemistry suggests formation in post-subduction, continental rift tectonic setting)

Siagian, H.P. & Widijono (2009)- The possibility of hydrocarbon trap and its potential in the North Bone Basin, based on geological and geophysical data. Jurnal Sumber Daya Geologi 19, 1, p. 63-76.
(online at: http://jgsm.geologi.esdm.go.id/index.php/JGSM/article/view/194/186)
(Bone basin believed to have formed since Early Tertiary, as fore-arc basin, underlain by pre-Tertiary metamorphics, volcanics and metasediments (Latimojong and Pompangeo Complexes). Hydrocarbon presence demonstrated by gas seeps in Pongko and Malangke villages. Coarse clastic and limestone deposits such as fluvio-deltaic Toraja and Lamasi Fms may be potential reservoirs; shales in Lamasi and Toraja Fms potential petroleum source rocks. Gulf Oil 1972 BBA 1X well in N part of Bone Bay TD at 10,521' in M Miocene)

(online at: http://jgsm.geologi.esdm.go.id/index.php/JGSM/article/view/219/209)
('Identification of ancient volcanoes in Sapaya, South Sulawesi, from remote sensing data '. S Arm of Sulawesi Island is Tertiary volcanic arc, represented by Camba Fm. Satellite imagery interpretation reveals two ancient volcanoes in Sapaya area and surroundings: (1) M Miocene- Pliocene Sapaya volcano eroded cone and (2) Pliocene Bantoloe volcano eroded cone. Sapaya Volcano may be controlled by Tethyan type subduction/ collision between Australian micro continental and Eurasian continent plates)

Sidarto & Wahyono (2001)- Kaitan antara struktur geologi dan endapan batubara di cekungan Karama, Sulawesi. Geol. Res. Dev. Centre (GRDC), Bandung, Spec. Publ. 26, p. 15-28.
('Link between structural geology and coal deposits in Karama basin, W Sulawesi'. Toraja Fm Late Eocene coal seams folded and thrusted in Late Miocene- Early Pliocene. Coal rank locally increases along fault zones. Above coal Late Eocene limestone with Discocyclina and Pellatispira)

Sidarto & Wahyono (2002)- Pemodelan geologi cekungan batubara di daerah Baraka, Enrekang, Sulawesi Selatan. J. Geologi Sumberdaya Mineral 12, 130, p. 2-18.
('Geologic model of the coal basin in the Baraka area, Enrekang, S Sulawesi'. Eocene coals of Toraja Fm rift section in Toraja Basin, N part of S Sulawesi. Overlie U Cretaceous Latimojong Fm and overlain by Late Eocene limestone. Three seams, Titok, Sangbuah and Batunoni-Lapin. Exposure of coal after Late Miocene-Pliocene folding event (see also Wahyono and Sidarto 2002))

Silver, E.A. (1981)- A new tectonic map of the Molucca Sea and East Sulawesi, Indonesia, with implications for hydrocarbon potential and metallogenesis. In: A.J. Barber & S. Wiryosujono (eds.) The geology and tectonics of Eastern Indonesia, Proc. CCOP-IOC SEATAR Working Group Mtg., Bandung 1979, Geol. Res. Dev. Centre (GRDC), Bandung, Spec. Publ. 2, p. 343-347.
(New fault zones discovered during Scripps 1976-1979 cruises and land expeditions: (1) Sula Thrust at N side Banggai- Sula Platform, (2) W continuation of Sorong FZ and (3) E extension of Batui Thrust which bounds upthrusted E Sulawesi ophiolite (which also forms Gorontalo basin basement, and emplacement was complete in Pliocene or earlier). Also mapped recently active Tolo Thrust E of Sulawesi and Buton)

Silver, E.A., Y. Joyodiwiryo & R. McCaffrey (1978)- Gravity results and emplacement geometry of the Sulawesi ultramafic belt, Indonesia. Geology 6, p. 527-531. *(also in Geol. Res. Dev. Centre, Spec. Publ. 2, p. 313-319)*
(SE arm Sulawesi gravity highs at schist ultramafic contacts indicate thick ultramafic rocks there, possibly dipping under schist. Gravity effect of ultramafics decreases E away from schist)

Silver, E.A., R. McCaffrey, Y. Joyodiwiryo & S. Stevens (1983)- Ophiolite emplacement by collision between the Sula Platform and the Sulawesi arc, Indonesia. J. Geophysical Research 88, p. 9419-9435.

(Large ophiolite belt from Miocene collision of Sulawesi island arc and continental Sula Platform. Batui thrust separates ophiolite from deformed sedimentary rocks along edge of Sula Platform and continues E from Sulawesi along S margin of Gorontalo basin. Sulawesi ophiolite traced offshore to oceanic crust basement of Gorontalo basin. Ophiolite melange underlies harzburgites on SE Arm beneath low-angle thrusts. Melange several 100m thick thrust packets of serpentine and red shale matrix and N to NE dipping foliation, consistent with significant N-ward component of lower plate movement, probably Sula platform margin. Ophiolite emplaced by oblique convergence of Sula platform along S edge of Gorontalo basin. Gorontalo basin probably forearc basin with ophiolite basement. Presence of dunite in Colo volcanic products in Tomini Bay indicate magma went through through oceanic material, possibly part of E Sulawesi Ophiolite)

Silver, E.A., R. McCaffrey & R.B. Smith (1983)- Collision, rotation, and the initiation of subduction in the evolution of Sulawesi, Indonesia. J. Geophysical Research 88, p. 9407-9418.
(Sulawesi shaped as result of collision with Sula platform, resulting in rotation of N volcanic arm and accretionary wedge of N Sulawesi trench. N Sulawesi trench changes laterally from no active deformation in E to a wide accretionary wedge in W. Early thrusting produced steep frontal slope (8°-16°), indicative of high basal shear stress, more advanced (W) zone of thrusting produces gentle slope (2°). Paleomagnetic data suggest post-Late Eocene counter-clockwise rotation of N Arm. Convergence between N Banda Basin and SW Sulawesi documented by Tolo thrust. S end of thrust projects toward Buton, but structural relations not clear)

Simandjuntak, T.O. (1980)- Wasuponda melange. Proc. 8th Ann. Conv. Indon. Assoc. Geol. (IAGI), Bandung, p.
(First description of C Sulawesi Wasuponda melange. Contains eclogite)

Subandrio, A.S. (2006)- Diagenetic alteration in Late Miocene carbonate of Tacipi area, South Celebes. Proc. 35th Ann. Conv. Indon. Assoc. Geol. (IAGI), Pekanbaru 2006, 10p.
(Tacipi reefal carbonate platform in Sengkang Basin, S Sulawesi mainy homogenous boundstones at top and packstones with local grainstones, and wackestones at bottom. Four reef facies identified: patch reef, barrier reef, fore reef and lagoon. Extensive freshwater leaching created biomoldic and vug pores)

Subandrio, A.S. & E. Usman (2011)- Diagenetic features of paleo lagoonal reef of Tacipi Area, South Celebes. Bull. Marine Geol. 26, 2, p. 95-104.
(online at: http://ejournal.mgi.esdm.go.id/index.php/bomg/article/view/37/38)
Late M Miocene- E Pliocene Tacipi Lst exposed in Tacipi area, Sengkang Basin, in lagoonal facies. Limestones mainly homogenous boundstones on top and packstones with local grainstones, and wackestones at base. Extensive freshwater leaching of fossil fragments and calcareous cement created moldic and vug porosity)

Subarsyah & Sahudin (2010)- Identifikasi sub-cekungan di cekungan Tomini bagian Selatan, berdasarkan penampang seismik 2D dan anomali gaya berat. J. Geologi Kelautan 8, 2, p. 95-104.
(online at: http://ejournal.mgi.esdm.go.id/index.php/jgk/article/view/190/180)

Subroto, E.A., B.Y. Afriatno & P. Sumintadireja (2007)- Prediction of the biogenic gas occurrences in Indonesia based on studies in East Java and Tomori (Central Sulawesi). Jurnal Teknologi Mineral (ITB), 14, 3, p. 115-124.
(online at: www.fttm.itb.ac.id/galeri/prediction.pdf)
(Biogenic gas dry (>99% methane), light carbon-isotopes (-61 to -67‰) and bacterial in origin. One of fields producing biogenic gas in E Java Basin. Sediments most likely producing biogenic gas from Plio-Pleistocene, characterized by high sedimentation rates, low geothermal gradients and high organic matter content)

Subroto, E.A., B. Priadi & B. Yulian (2004)- Study on gas samples collected from Tanjung Api and Tomori area, Sulawesi: abiogenic, biogenic, or thermogenic? Buletin Geologi (ITB) 36, 3, p. 117-124.
(Analysis of 3 gas samples from E Sulawesi. Two are from Donggi 1 well and are biogenic. Tanjung Api surface seep sample 53% hydrocarbon gas (98.2% methane, 1.5% ethane) and unusually heavy d13C isotopes. Origin is dubious: possibly abiogenic or post-mature or biodegraded)

Sudarmono (1999)- Tectonic and stratigraphic evolution of the Bone Basin, Indonesia: insights to the Sulawesi collision complex. Proc. 27th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, p. 531-534.
(Bone Basin is subduction complex/ suture between Sundaland and Gondwana-derived micro-continent that evolved into submerged intra-montane basin. Paleogene- E Miocene forearc stage with W-dipping subduction complex. M-L Miocene W-ward convergence of microcontinents toward subduction complex changed deposition and basin configuration. M Miocene collision with accretionary complex, followed by collision with W Sulawesi. Collision led to E-ward rotation of SE Sulawesi, with rifting and submergence of S part of basin. Compression from collision caused major back-thrust systems of W-verging Kalosi and Majene fold belts in W Sulawesi. Colliding plates began to lock in Pliocene, and continued plate convergence was accommodated by strike-slip along Walanae, Palu Koro and other faults. Bone Basin submerged into intra-montane basin setting. Clastic sediments from surrounding mountains to E, N and W prograded S to depocenter. Strike-slip still active)

Sudijono (2005)- Biostratigraphy and the depositional environment of the Toraja Limestone at the Nanggala river section, Toraja, South Sulawesi. J. Sumber Daya Geologi 15, 1 (148), p. 57-74.
(80m thick Toraja Fm limestone member at Nanggala River, 10km NE of Rantepao. Lower part Middle Eocene (Ta3) age, with Alveolina and Nummulites javanus. Upper ~10m Late Eocene (Tb) with Pellatispira madaraszi and abundant Discocyclina/ Asterocyclina. Overlying volcanic sst-claystone facies (Lamasi Volcanics?) with abundant Late Eocene (P15) planktonic foraminifera (Hantkenina, Gr. cerroazulensis, Pseudohastigerina micra). Toraja Fm underlain unconformably by Cretaceous Latimojong Fm metasediments)

Sudijono (2005)- On the age of the Makale Formation of the Makale-Totumbang Road section, Tana Toraja, South Sulawesi. J. Sumber Daya Geologi 15, 2 (149), p. 3-23.
(Makale Fm ~500-1000m thick marl-limestone formation, well exposed between Makale and Totumbang, in NE part of South Arm. Affected by N-S trending, West directed thrusting. Sampled part mainly zone Tf1, possibly also Te5 near base and Tf2 at top. Presence of Austrotrillina howchini, Cycloclypeus (Katacycloclypeus) annulatus, Flosculinella bontangensis, Miogypsina antillea, etc. Age late E Miocene- early M Miocene)

Sudradjat, A. (1982)- Geologi Lembah Palu Sulawesi Tengah dengan menggunakan teknik penginderaan jauh. Masters Thesis Inst. Teknologi Bandung (ITB), p. *(Unpublished)*
('Geology of the Palu valley, Central Sulawesi, using remote sensing techniques'. Palu-Koro Valley 250 km long, is reflection of sinistral Palu-Koro strike slip fault, with active movement estimated at 2-3.5mm to 14-17 mm/ year, totaling 3.25 km. Palu-Koro fault separates two different terranes)

Sufriadin (2008)- Comparative petrography of Paleogene and Neogene coal deposits from Southern Arm Sulawesi. Proc. 37th Ann. Conv. Indon. Assoc. Geol. (IAGI), Bandung, 1, p. 672-681.
(Petrography of 18 coal samples from SW Sulawesi. Toraja Fm Paleogene coals higher vitrinite and liptinite than Neogene Fm coal, which have more inertinite and higher mineral matter (clay, iron sulfides, minor carbonate). Vitrinite reflectance wide range in Paleogene (0.35- 0.86%). Neogene coals narrower range (0.44-0.60%; lignite to HV Bituminous A coal). Maturity of some coals affected by igneous intrusions)

Sufriadin, K. Angayana & A. Sudarsono (2002)- Karakteristik mineralogi batubara daerah Tondongkurah, Kabupaten Pangkep, Sulawesi Selatan. In: Proc. 31st Ann. Conv. Indon. Assoc. Geol. (IAGI), Surabaya, p. 185-192.

('Stratigraphic relationship between the Banggai-Sula Islands and Sulawesi's East arm'. Differerent types of basement and overlying rocks, but both overlapped by similar Late Miocene-Pliocene Celebes Molasse)

Surono (1994)- A sedimentologic investigation of the Southeast Arm of Sulawesi with special reference to the Kendari area. Ph.D. Thesis, University of Wollongong, Australia, p. 1-211 + Appendices, figures, tables.
(online at: http://ro.uow.edu.au/theses/1393/)
(Collision complex in SE Arm of Sulawesi consists of SE Sulawesi continental terrane, overthrust by ophiolite E Sulawesi Ophiolite Belt in Oligocene- M Miocene and overlain by synorogenic E Miocene Sulawesi Molasse. SE Sulawesi continental terrane consists of metamorphic basement unconformably overlain by clastics-dominated Late Triassic Meluhu Fm (basal part fluvial, grading upward into deltaic and marine facies) and carbonate-dominated Eocene- E Oligocene Tampakura Fm (incl. oolites). Paleolatitude of basin at time of Triassic Meluhu Fm deposition ~20°S. Basal Sulawesi Molasse unconformably over Paleogene, with Matarape conglomerate with ophiolite clasts, overlain by E Miocene limestone with Te5 larger forams (Miogypsinoides, Spiroclypeus, Lepidocyclina) (Sample 6A; identified by Chaproniere 1993) and NN3 nannofora)

Surono (1994)- Stratigraphy of the Southeast Sulawesi continental terrane, eastern Indonesia. J. Geologi Sumberdaya Mineral 31, 4, p. 4-11. *(also reprinted in Surono 2008)*

(SE Arm of Sulawesi continental terrane composed of Mesozoic metamorphic rocks, intruded by granites. Unconformably overlain by Late Triassic Meluhu Fm fluvial clastics (Carnian- Norian?; with Falcisporites), and U Jurassic- Lw Cretaceous marine deposits of Tetambahu Fm (with Tithonian- Hauterivian radiolaria incl. Archaeodictyomitra and Thanarla). Unconformably overlain by Paleogene Tampakura Fm oolitic- dolomitic carbonates with Nummulites. SE Sulawesi and Bangai-Sula block stratigraphy similar to central PNG. Paleomagnetic analysis suggest SE Arm part of continental terrane, deposited 20°S of present location in Late Triassic, at N Australian (PNG) continental margin. Emplacement of poorly-dated E Sulawesi Ophiolite complex over SE Sulawesi continental block margin in latest Oligocene (= collision of SE Sulawesi- Buton?). Post-collisional Sulawesi Molasse unconformable over molasse and older formations, with Pandua Lst interbeds with E Miocene larger foraminifera)

Surono (1995)- A petrographic study of an oolitic limestone succession of the Eocene-Oligocene Tampakura Formation, South-East Sulawesi, Indonesia. J. Geologi Sumberdaya Mineral 5, 50, p. 2-11. *(also reprinted in Surono 2008, p. 103-118)*
(?Eocene Tampakura Fm limestone unconformable between underlying Late Triassic Meluhu Fm and overlying Mio-Pliocene Sulawesi Molasse. Oolites dominant, minor lime mudstone locally rich in globigerinid planktonic foraminifera, some dolomite)

Surono (1995)- Sedimentology of the Tolitoli Conglomerate Member of the Langkowala Formation, Southeast Sulawesi, Indonesia. J. Geologi Sumberdaya Mineral 5, 46, p. 1-7.
(also reprinted in Surono 2008, p. 161-173. E-M Miocene Tolitoli conglomerates of SE Sulawesi unconformable on Triassic clastics and Paleogene limestone. Deposited in braided river/ alluvial fan environment, with general paleocurrent direction to West. Conglomerate clast mainly derived from Late Triassic Meluhu Fm sandstones, with minor contribution from Tampakura Fm. No fossils, but age derived from position unconformably over Oligocene and under Late Miocene-Pliocene Boepinang Fm)

(E Sulawesi map between 1 and 2°S, NW side of Tolo Bay, mapped in 1981. Two terranes: (1 Banggai-Sula Platform with Carboniferous metamorphics and Permo-Triassic granites and (2) E Sulawesi ophiolite belt, composed of E Cretaceous ultrabasics overlain by U Cretaceous Matano Fm deep marine pelagic cherts and calcilutites. Terranes collided in M Miocene, creating Late Miocene- Pliocene molasse. Quaternary uplift. Oil seeps in several places along Batui thrust, the collision zone between ES ophiolite and BS Platform. Miocene Kolokolo melange near Batui Thrust))

Surono & D. Sukarna (1993)- Geology of the Sanana Sheet, Maluku, scale 1:250,000. Geol. Res. Dev. Centre (GRDC), Bandung.
(Geology of eastern Banggai-Sula Islands, SE of E Sulawesi (E Taliabu, Mangole, Sanana). Oldest formation ?Carboniferous metamorphics and ?Permo-Triassic Banggai granite intrusives with >400m thick co-magmatic Mangole Fm volcanic breccias and tuffs. Small occurrence of ~50-100m thick Triassic? Nofanini Fm coral-mollusc limestone off S coast of Mangole. Unconformably overlain by thick M-L Jurassic Bobong and Buya Fms with common ammonites, and Late Cretaceous Tanamu Fm Globotruncana marl-limestone)

Surono & D. Sukarna (1995)- The Eastern Sulawesi Ophiolite Belt, Eastern Indonesia. A review of its origin with special reference to the Kendari area. J. Geologi Sumberdaya Mineral 5, 46, p. 8-16.
(Also in Ofiolit di Sulawesi, Halmahera, dan Kalimantan, Geol. Res. Dev. Centre (GRDC), Bandung, Spec. Publ. 28 (2001), p. 1-10 and reprinted in Surono 2008). Mafic-ultramafic rocks widespread in SE arm of Sulawesi. Peridotite dunite, etc. with gabbro and basalt characterize mid-oceanic ridge type ophiolite complex.

Ophiolite probably was thin widespread layer covering continental terrane. Late Cretaceous- Late Oligocene age (does not fit with reported E Cretaceous radiolaria in overlying sediments?; JTvG). Paleomagnetic results suggest formation at 17-24°S in Late Cretaceous and rotated CW about 60° (Mubroto). Ophiolite debris abundant in M Miocene and younger Sulawesi Molasse. SE arm ophiolite probably thrust over SE Sulawesi continental terrane in M-Late Oligocene, while in E arm it occurred in E Miocene)

Surono & D. Sukarna (1996)- Sedimentology of the Sulawesi molasse in relation to Neogene tectonics, Kendari area, Eastern Indonesia. Proc. 6th Int. Congress Pacific Neogene Stratigraphy, IGCP355, Serpong 1995, p. 57-72.
(Reprinted in Surono 2008, p. 175-192)
(Miocene- Pliocene Sulawesi Molasse post-collisional deposits, with E Miocene forams (Spiroclypeus) and nannofossils (NN3) in limestones in upper part of basal Matarape Fm conglomerates. Ophiolite-derived fragments dominant in lower molasse, decreasing in size upsection, and more detritus from SE Sulawesi continental terrane, suggesting ophiolite formed thin cover over SE Sulawesi terrane)

(online at: (online at: https://resolver.kb.nl/resolve?urn=MMKB21:041182000:pdf)
(Appendix in Brouwer, 1934. Documentation of Eocene limestones with Pellatispira and Miocene limestones in different parts of Sulawesi. Several conglomeratic limestones from NE part of SE arm (Bahumpombini/ Bungku area) contain E Miocene larger foraminifera (Te5; Miogypsina, Spiroclypeus and Lepidocyclina (Eulepidina)), but also reworked clasts of U Cretaceous Globobotruncana pelagic limestone, radiolarian chert and serpentine (suggesting E Miocene or older uplift of E Sulawesi ophiolite terrane; JTvG))

Van Leeuwen, T. (1981)- The geology of southwest Sulawesi with special reference to the Biru area. In: A.J. Barber & S. Wiryosayono (eds.) The geology and tectonics of Eastern Indonesia. Geol. Res. Dev. Centre (GRDC), Bandung, Spec. Publ. 2, p. 277-304.
(SW Sulawesi Biru area E of Ujung Pandang (Makassar) almost complete U Cretaceous- U Miocene record. Basement is Bantimala Complex metamorphics (K/Ar age 111 Ma), ultrabasic rocks and tectonic melange with NE-dipping radiolarian cherts, clastics and igneous rocks. Metamorphics unconformably overlain by latest Jurassic-E Cretaceous sands, shale and radiolarian cherts. Sands near base with metamorphic and ultramafic clasts. Flysch-type U Cretaceous folded and uplifted before deposition of thick Langi Fm andesitic volcanics (Paleocene K/Ar age near base; upper part with Late Eocene coals and limestones with Pellatispira). Conformably overlain by ~400m U Eocene- M Miocene Tonasa Limestone (Tb- Lower Tf, but mid-Oligocene unconformity). Unconformably overlain by >1000m thick M and U Miocene Sopo-Walanae-Lemo Fm volcanics (~17- ~5 Ma?). Mid-M Miocene folding and uplift event, associated with 40° CCW rotation of area. Also unconformity at base of U Miocene Lemo andesitic volcanics and Plio-Pleistocene folding-uplift event)

Van Leeuwen, T., C.M. Allen, M. Elburg, H.J. Massonne, J.M. Palin & J. Hennig (2016)- The Palu Metamorphic Complex, NW Sulawesi, Indonesia: origin and evolution of a young metamorphic terrane with links to Gondwana and Sundaland. J. Asian Earth Sci. 115, p. 133-152.
(Young metamorphic core complexes of Palu (PMC) and Karossa, mainly in 'neck' of NW Sulawesi. N part mainly amphibolite (oceanic parentage?), S part mainly biotite schists (meta-sediments) with some gneiss (meta-granite). Local peridotite. Rocks resided at depths of 60-120 km during part of their histories. S part overlain by U Cretaceous Latimojong Fm clastics and volcanics (but parts of PMC also metamorphosed Latimojong Fm). Zircon ages of metamorphics suggest metamorphism event at 3-4 Ma of older protoliths (210-230 Ma/ Late Triassic and ~80-120 Ma/M Cretaceous). Rapid cooling exhumation in latest Miocene- M Pliocene (Ar/Ar cooling ages 6.0- 3.6 Ma). Composite terrane with (1) gneiss unit of Gondwana origin (but presence of Late Triassic meta-granitoids and recycled Proterozoic zircons suggest W Sulawesi Block origin in New Guinea region, not NW Australian margin, as suggested in recent reconstructions?), (2) schist unit composed of low-metamorphic turbidites deposited in Late Cretaceous- E Tertiary along SE Sundaland margin, and (3) slivers of amphibolite with oceanic crust characteristics)

Van Leeuwen, T., C.M. Allen, A. Kadarusman, M. Elburg, J.M. Palin, Muhardjo & Suwijanto (2007)- Petrologic, isotopic, and radiometric age constraints on the origin and tectonic history of the Malino metamorphic complex, NW Sulawesi, Indonesia. J. Asian Earth Sci. 29, p. 751-777.
(Malino Metamorphic Complex (MMC) at W end of Sulawesi N arm mica schists and gneisses from proximal turbidite and granitoid protoliths, with intercalations of greenschist, amphibolite, marble and quartzite. Devonian- Early Carboniferous age, Archean-Proterozoic inherited zircons, and isotopic signatures indicate terrane derived from New Guinea-Australian margin. Similarities with Birds Head basement suggests common origin. Greenschists around MMC from adjacent autochthonous Paleogene. Barrovian progression from greenschist through epidote-amphibolite to amphibolite. P-T estimations suggest 27-30 km burial. Cooling ages 23-11 Ma, and 7 Ma age for unconformably overlying volcanic rocks, indicate Miocene exhumation. Two tectonic scenarios: (1) continental fragment docked with Sulawesi in Mesozoic and exhumed as metamorphic core complex in Miocene; (2) subducted beneath N arm in Late Oligocene, then rapidly returned to surface)

Van Leeuwen, T.M. & Muhardjo (2005)- Stratigraphy and tectonic setting of the Cretaceous and Paleogene volcanic-sedimentary successions in Northwest Sulawesi, Indonesia: implications for the Cenozoic evolution of Western and Northern Sulawesi. J. Asian Earth Sci. 25, p. 481-511.

(W Sulawesi is rifted continental margin of E Sundaland. Metamorphic basement, partly of Australian origin, overlain by Late Cretaceous Latimojong Fm fore-arc turbidites. M Eocene- earliest Miocene transgressive cycle: syn-rift siliciclastics, nummulitic limestone and associated shelf sediments to deeper marine mudstones and turbidites (Budungbudung and Tinombo Fms). At same time N Sulawesi oceanic island arc, with bimodal Papayato volcanism on oceanic crust. Cretaceous- Paleogene volcanic and sedimentary suites contrasting tectonic setting of two provinces. Relationship between two domains not clear: probably formed continuous belt through Cenozoic, definitely connected by E Miocene. Paleogene deformation in N part of NW Sulawesi and unconformable relationship with overlying formations may be result of collision of N arm with Australian-derived continental fragment in E Miocene, or M Miocene formation of extensional metamorphic core complex. Second major tectonic event Pliocene-ongoing, affects entire region)

Van Leeuwen, T.M. & P.E. Pieters (2011)- Mineral deposits of Sulawesi. In: N.I. Basuki (ed.) Proc. Conf. Sulawesi Minerals Resources 2011, Manado, MGEI/IAGI, p. 1-109.
(Major review of Sulawesi mineral deposits. Same as Van Leeuwen & Pieters (2013))

Van Leeuwen, T.M. & P.E. Pieters (2013)- Mineral deposits of Sulawesi. Geological Agency, Ministry of Energy and Mineral Resources, Bandung, p. 1-127.
(Extensive overview of mineral deposits of N, W and E Sulawesi Provinces, set in historic and geologic contexts. Sulawesi has complex geology with wide variety of mineralization styles, including porphyry Cu-Au, porphyry Mo, epithermal, metamorphic and sedimentary Au, lateritic nickel and Fe, etc.. Gold mining started in 1896, nickel in 1938. By world standards Sulawesi is underexplored)

Van Leeuwen, T.M., E.S. Susanto, S. Maryanto, S. Hadiwisastra, Sudijono, Muhardjo & Prihardjo (2010)- Tectonostratigraphic evolution of Cenozoic marginal basin and continental margin successions in the Bone Mountains, Southwest Sulawesi, Indonesia. J. Asian Earth Sci. 38, 6, p. 233-254.
(Bone Mts in SW Sulawesi composed of Oligocene- Lower Miocene transtensional marginal basin Bone Gp (MORB-like volcanics and interbedded hemipelagic mudstones), juxtaposed against Eocene- Miocene continental margin Salokalupang Gp. Latter: (1) M- U Eocene volcaniclastics with limestone intercalations in upper part, reflecting arc volcanism and carbonate development along Sundaland margin; (2) Oligocene calc-arenites, deposited on passive margin, and (3) Lower- M Miocene clastics- volcanics, formed in extensional regime without subduction. At ~14-13 Ma start of widespread extension in SW Sulawesi, with potassic volcanism (Camba Fm), reaching peak 1 Ma year later with juxtaposition of Bone Gp against Salokalupang Gp along Walanae strike-slip fault. Potassic volcanism continued to end Pliocene, locally to Quaternary)

Van Leeuwen, T.M., R. Taylor, A. Coote & F.J. Longstaffe (1994)- Porphyry molybdenum mineralization in a continental collision setting at Malala, Northwest Sulawesi, Indonesia. J. Geochemical Exploration 50, p. 279-315.
(Malala deposit in NW Sulawesi only known porphyry Molybdenum in Indonesia, associated with mainly granitic intrusives (Malala porphyries) as late differentiates in roof zone of Dondo batholith. Intrusives part of 600 km belt of granites and granodiorites, emplaced in continental margin ('W Sulawesi') in Late Miocene-Pliocene, during and following collisions between several microcontinents and Sulawesi western magmatic arc/eastern subduction complex. Granitoids from partial melting of lower crust (possibly underthrusted Precambrian- Paleozoic continental crust) due to lithospheric thickening in continental collision regime)

Van Schelle, C.J. (1889)- Verslag over het voorkomen van goudvoerende aderen bij Sumelatta (Residentie Menado). Jaarboek Mijnwezen Nederlandsch Oost-Indie 1889, Technisch Admin. Ged., Verhandelingen, p. 5-38.
('Report on the occurrence of gold-bearing veins near Sumelatta (Residency Menado)'. Early investigation of gold near Sumalata along the north coast of North Sulawesi, with potential concessionaire Parmentier in 1886. Gold mined by natives since 1813, directed by the Rajah of Limbotto, who claimed 20% of gold mined. Many small shafts up to 14m deep. By 1886 mine works were mostly abandoned)

Van Schelle, C.J. (1889)- Verslag van een onderzoek naar de waarde van bekende goudvindplaatsen in de afdeeling Gorontalo (Res. Menado). Jaarboek Mijnwezen Nederlandsch Oost-Indie 1889, Technisch Admin. Ged., Verhandelingen, p. 39-55.

(online at: www.gsj.jp/Pub/News/pdf/2002/05/02_05_05.pdf)

Wakita, K., Munasri, J. Sopaheluwakan, I. Zulkarnain & K. Miyazaki (1994)- Early Cretaceous tectonic events implied in the time-lag between the age of radiolarian chert and its metamorphic basement in Bantimala area, South Sulawesi, Indonesia. The Island Arc 3, p. 90-102.
(Bantimala Complex of S Sulawesi mainly melange, chert, basalt, ultramafic rocks and high-P metamorphics. Radiolarian assemblage from unconformably overlying chert Mid-Cretaceous (late Albian-early Cenomanian= around 100 Ma), while K-Ar ages from schist range from 132-114 Ma. This suggests brief tectonic event followed by quick waning tectonism during Albian-Cenomanian transgression)

Wakita, K., J. Sopaheluwakan, K. Miyazaki, I. Zulkarnain & Munasri (1996)- Tectonic evolution of the Bantimala Complex, South Sulawesi, Indonesia. In: R. Hall & D. Blundell (eds.) Tectonic evolution of Southeast Asia, Geol. Soc., London, Spec. Publ. 106, p. 353-364.
(Bantimala Complex NE-dipping tectonically stacked slices, composed mainly of high-P metamorphics and radiolarian chert, but also E-M Jurassic sandstones and overlain by mid-Cretaceous radiolarites and Late Cretaceous turbiditic series. Ages of metamorphics suggest oceanic plate subduction in Late Jurassic- earliest

Cretaceous. Subduction ceased in Albian. High-P schists exhumed due to collision of Gondwana-derived microcontinents)

Walpersdorf, A., C. Rangin & C. Vigny (1998)- GPS compared to long-term geologic motion of the North arm of Sulawesi. Earth Planetary Sci. Letters 159, p. 47-55.
(Paleomagnetic data from N arm of Sulawesi indicate ~20-25° rotation since 5 Ma, suggesting 200-250 km of left-lateral displacement along Palu-Koro fault. Similar Palu fault displacement derived from magnetic anomalies of Celebes seafloor, which implies 200- 250 km of oceanic crust subducted at N Sulawesi trench. Another marker for rotation derived from opening of Gulf of Tomini and NW migration of calc-alkaline subduction-related volcanism. GPS observation of 4 cm/year of left-lateral strike-slip across Palu fault fit well with N arm motion of 4-5 cm/year. Current rates from GPS approximate long-term rates)

Walpersdorf, A., C. Vigny, P. Manurun, C. Subarya & S. Sutisna (1999)- GPS observation of the Triple Junction, Indonesia. In: The GEODYnamics of S and SE Asia (GEODYSSEA) Project, GeoForschungs Zentrum, Potzdam, STR 98/14, p. 226-238.

Walpersdorf, A., C. Vigny, C. Subarya & P. Manurung (1998)- Monitoring of the Palu-Koro Fault (Sulawesi) by GPS. Geophysical Research Letters 25, 13, p. 2313-2316.
(online at: http://onlinelibrary.wiley.com/doi/10.1029/98GL01799/epdf)
(5 years of GPS monitoring shows ~3.4 cm/yr left-lateral strike slip on Palu Fault)

Wanner, J. (1910)- Beitrage zur Geologie des Ostarms der Insel Celebes. Neues Jahrbuch Mineral. Geol. Palaontologie, Beilage Band 29, p. 739-778.
('Contributions to the geology of the East Arm of Sulawesi Island'. Results of 2-month geological reconnaissance in 1905, mainly in SE side of E Arm, along Peleng Straits, near Toeli, Nambo, etc. In around Central Mountains describes (1) ultrabasic rocks, (2) rel. widespread Eocene limestones with Alveolina, Discocyclina and Nummulites, reminescent of Alveolina Limestone of Misool; (3) E Miocene shallow water carbonates with Lepidocyclina and Miogypsina; (4) Celebes molasse conglomerates 1200m thick or more (sandy marls and limestone near base with Pliocene planktonic and larger foraminifera, incl. Globorotalia tumida, no lepidocyclinids; JTvG), (5) Quaternary raised coral reef terraces up to 400m above s.l. Near Toeli also probably Jurassic-age 'Toeli Limestone', reminescent of Buru Limestone. Along N coast (Tomini Bay) common gabbro and peridotite, with oil seep in Babason creek, a tributary of Lobu River. Gabbro appear to be intrusives in U Oligocene- E Miocene limestone with Spiroclypeus, Lepidocyclina)

('The geology of Sulawesi, especially from an economic point of view'. Brief summary of lecture on Sulawesi geology and indications of oil, coal and metals. No figures)

Wanner, J. & E. Jaworski (1931)- Liasammoniten von Jamdena und Celebes. Neues Jahrbuch Mineral. Geol. Palaontologie, Beilage Band 66, B, p. 199-210.

('Liassic ammonites from Yamdena and Sulawesi'. Sulawesi ammonites from poorly known central part of East arm, collected by BPM geologist Weber. First records of E Jurassic ammonites from E Sulawesi (Arnioceras cf. seilaeve from dark grey sandy limestone as float in upper Balingara River, 20km SE of river mouth). Yamdena ammonites from Tasik Selwasa and Botenjahu mud volcano deposits include Echioceras wichmanni, Asteroceras sparsicostatum n.sp. and Arnioceras cf. arnouldi. Fauna and lithology very similar to 'grey cephalopod nodule marl' of Roti and Timor, described by Krumbeck (1922))

Watkinson, I.M. (2011)- Ductile flow in the metamorphic rocks of Central Sulawesi. In: R. Hall, M.A. Cottam & M.E.J. Wilson (eds.) The SE Asian gateway: history and tectonics of Australia-Asia collision, Geol. Soc. London, Spec. Publ. 355, p. 157-176.
(Gneisses, amphibolites and schists exposed along Palu-Koro Fault of W-C Sulawesi are part of regionally metamorphosed Mesozoic-Precambrian basement. In Palu and Neck regions of Sulawesi, ductile shear fabrics record low-angle W-ward extension. Further south in Palu valley, extension directed towards SW. Cross-cutting granitic dykes show foliation in neck region of Sulawesi occurred before ~44-33.7 Ma. In Palu valley it occurred before 5-3.5 Ma, precluding origin as result of Palu-Koro Fault activity. Ductile flow during either Eocene-Miocene mid-crustal extension above metamorphic core complex, Cretaceous subduction-related deformation in over-riding plate, or intracontinental deformation within Gondwana)

Watkinson, I.M. & R. Hall (2011)- The Palu-Koro and Matano faults, Sulawesi, Indonesia: evolution of an active strike-slip fault system. Geophysical Research Abstracts 13, EGU2011-8270, EGU Gen. Assembly 2011.
(Abstract only. Palu-Koro and Matano faults of Sulawesi important active strike-slip faults. Palu-Koro fault slip rate 32-45 mm/yr and left-lateral displacement about 200 km. Shorter Matano fault SE continuation and now in process of coalescing with Palu-Koro fault. Faults probably did not initiate before ~5 Ma)

Werdmuller, J.O. (1926)- Petrographische Untersuchung von Eruptivgesteinen des Pik von Maros in Sud-West-Celebes. Schweizerische Mineralogische Petrographische Mitteilungen. 6, 2, p. 205-254.
(online at: https://www.e-periodica.ch/digbib/view?pid=smp-001:1926:6232)
('Petrographic investigation of volcanic rocks of the peak of Maros in SW Sulawesi'. Descriptions of rocks from volcanic Maros Peak (phonolite; 1375m high) and associated igneous rocks (incl. marosite, named after Maros Peak; also shonkinite, trachyte, etc.). Rocks collected between 1895-1902 by Sarasin cousins and in 1904 by Schmidt. With photomicrographs of thin sections)

White, L.T., R. Hall & R.A. Armstrong (2014)- The age of undeformed dacite intrusions within the Kolaka Fault zone, SE Sulawesi, Indonesia. J. Asian Earth Sci. 94, p. 105-112.
(Dacite intrusions in strand of Kolaka Fault that crosses SE Arm of Sulawesi and N Bone Bay. Kolaka Dacite undeformed, with zircon ages between ~4.4 and 7 Ma. Rare inherited zircons, with ages between 8- 1854 Ma, show SE arm of Sulawesi is underlain by Proterozoic or younger material)

White, L.T., R. Hall & R.A. Armstrong, A.J. Barber, M.K. BouDagher-Fadel, A. Baxter, K. Wakita, C. Manning & J. Soesilo (2017)- The geological history of the Latimojong region of western Sulawesi. J. Asian Earth Sci. 138, p. 72-91.
(online at: http://searg.rhul.ac.uk/pubs/white_etal_2017%20Latimojong.pdf)
(Latimojong Metamorphic Complex in C-W Sulawesi is accretionary complex of metamorphic rocks tectonically mixed with cherts and ophiolitic rocks, overlain(?) by unmetamorphosed U Cretaceous Latimojong Fm distal turbidites (accretionary complex). Aptian-Albian radiolaria in chert float sample in Latimojong Metamorphic Complex. Foraminifera ages from Toraja Group (56-23 Ma), Makale Fm (20.5-11.5 Ma) and Enrekang Volcanic Series (8.0-3.6 Ma). Magmatic zircons record ~38, ~25 and 8.0-3.6 Ma phases of volcanism. Late Miocene- E Pliocene high-K Enrekang Volcanics (~ 3.9-7.5 Ma) and Palopo Granite (6.6-4.9 Ma) may be tied to crustal extension/ slab rollback. Miocene-Proterozoic inherited zircons in Pliocene igneous rocks support Proterozoic-Phanerozoic (193, 38-34 Ma) basement or sediments derived from these. Little evidence for Oligocene-Pliocene thrusting in Latimojong region)

Whitten, A.J., M. Mustafa & G.S. Henderson (1988)- The ecology of Sulawesi. Gadjah Mada University Press, Yogyakarta, p. 1-777. *(Reprinted 2002, Periplus Edition, 727p.)*

(Sulawesi Eocene- M Miocene syntectonic Tonasa carbonate platform developed W of volcanic arc and overlain by M-U Miocene volcanics. Greatest extent Late Eocene. Tectonics and volcanism influenced evolution and diachronous termination in 4 ways: (1) Paleogene volcanic activity limited E-ward extent of platform but

had little effect in W S Sulawesi. (2) Late Eocene faulting resulted in platform segmentation, localized drowning in hanging wall areas and subaerial exposure on footwall highs. (3) E-M Miocene faulting around early stages of volcanism in W S Sulawesi resulted in localized tilting of fault blocks, formation of new graben, and exposure of footwall highs. (4) M Miocene volcaniclastics influx buried remaining areas of shallow-water carbonates. Carbonate production contemporaneous with volcanism in areas shielded from volcaniclastic input)

(online at: www.repository.naturalis.nl/document/549740)
('A new Tertiary mollusc fauna from the Indies Archipelago'. Mollusc assemblage of 26 new species from Buton asphalt-bearing marls/ limestones, which are unconformable over folded Mesozoic sediments. Assigned Late Oligocene or E Miocene age (Later interpretations favor Late Miocene-Pliocene ages (e.g. Beets 1952, Keyzer 1953, Fortuin et al. 1990, Janssen 1999))

Martin, K. (1935)- Oligocaene Gastropoden von Buton. Leidsche Geol. Mededelingen 7, 2, p. 111-118.
(online at: www.repository.naturalis.nl/document/549589)
(‘Oligocene gastropods from Buton’. Molluscs from asphalt-bearing limestones of Buton 35 species, all extinct, suggesting pre-Neogene (Oligocene) age. Nine new gastropod species described here (since then age corrected as Mio-Pliocene; JTvG))

Martin, K. (1937)- Die oligocaenen Mollusken von Buton als Auswurflinge eines Schlammsprudels betrachtet. Leidsche Geol. Mededelingen 8, p. 311-314.

(online at: www.repository.naturalis.nl/document/549248)
('The Oligocene molluscs from Buton, interpreted as clasts of a mud volcano'. Molluscs from Buton originally dated as Oligocene, but Sampolakosa Fm now regarded as Late Neogene age by Hetzel (1936). Older material may be explained as mud volcano ejecta (see also Beets 1952, who argues for Miocene-Pliocene age of Buton molluscs)

Milsom, J. (1992)- Structure and collision history of the Buton continental fragment, Eastern Indonesia. AAPG Int. Conf., Sydney 1992, Search and Discovery Art. 91015. *(Abstract only)*
(Fragment of Australian continental margin now exposed on Buton, SE of Sulawesi. Asphalt reserves support significant local industry. Buton Terrane underwent significant relative rotations and extends beneath adjacent island of Muna. Tukang Besi platform E of Buton may be distinct, unrelated, unit. Ophiolitic rocks exposed on Buton not attached to deep roots and are thin overthrust sheets not marking terrane boundary)

Milsom, J., J. Ali & Sudarwono (1999)- Structure and collision history of the Buton continental fragment, Eastern Indonesia. American Assoc. Petrol. Geol. (AAPG) Bull. 83, p. 1666-1689.
(Buton is Australian-derived continental terrane. Gravity defines present-day W limits of Buton terrane and suggests terrane includes Tukang Besi platform in E. Ophiolitic rocks on Buton no deep roots, but thin and isolated overthrust sheets, and do not mark terrane boundary. Buton separated from Australia in Jurassic or Late Triassic, and collided with Eurasian margin in SE Sulawesi in Oligocene or E Miocene. Extension dominated recent history of area, producing minor separation of Tukang Besi from Buton and dispersion of other fragments, some of which have been incorporated in collision zone in Outer Banda arc. Oil seeps and asphalt deposits of Buton show hydrocarbons can be sourced from these fragments)

Mubroto, B. & J. Ali (1998)- Tectonic rotations indicated by the late Cenozoic paleomagnetic rocks in Buton Island, Southeast Sulawesi, Indonesia. In: J.L. Rau (ed.) Proc. 33rd Sess. Coord. Comm. Coastal and Offshore Programmes E and SE Asia (CCOP), Shanghai 1996, 2, p. 246-258.
(Buton island continental fragment impacted, accreted and uplifted when Tukang-Besi platform began docking with SE Sulawesi in Pliocene (2-3 Ma). Two major structural orientations; N-S in N part, NE-SW in S part, suggesting 60° clockwise rotation of S Buton with respect to N Buton (Fortuin et al. 1989). Data from 41 paleomagnetic sites from Miocene-Pliocene Tondo and Sampolakosa Fms suggest N Buton rotations of ~30° CW and CCW, probably local, C Buton small rotations, and S Buton 30-60° CW rotation. Data imply thin-skinned sheets associated with collision)

(Asphalt deposits of Buton Island, known since 1920's, contain 15-35% asphalt/ bitumen, mainly impregnations in Pliocene Sampolakosa Fm carbonates and Miocene Tondo Fm sandstones, in uplifted and intensively thrusted anticlines. Asphalt deposits biodegraded crude oils derived from marine Type II kerogen, tied to Triassic calcareous shales and bituminous limestones of Winto Fm. Sulfur content generally high (2.5- 9.3%.). Five exploration wells on Buton between 1976-2012, all dry, some with oil shows in Miocene. Nunu oil seep on W Buton contains oleanane, indicating Tertiary source)

Scheiber, R. (1932)- Der Boetonasphalt mit seine Foraminiferen. Asphalt und Teer, Strassenbautechnik 32, p. 659-661.
('The Buton asphalt with its foraminifera'. Obscure reference reporting presence of planktonic foraminifera Pulvinulina (=Globorotalia) menardii and Orbulina universa in asphalt-bearing rocks of Buton. This clearly suggests M Miocene or younger age, not Oligocene as originally suggested by Martin (1934), etc.)

Sikumbang, N., P. Sanyoto, R.J.B. Supandjono & S. Gafoer (1995)- Geologic map of the Buton Sheet, Southeast Sulawesi, 1:250, 000. Geol. Res. Dev. Centre (GRDC), Bandung.
(Geologic map SE Sulawesi Buton/ Muna islands between 4.15 and 5.45° S. Oldest rocks pre-Triassic Mukito Fm metamorphics. Jurassic-Triassic low-metamorphic Doole Fm. Oldest sediments Triassic Winto Fm shale, ~750m thick sandstone and limestone, with bivalves Halobia, Daonella and Monotis salinaria, ammonite Juvavites ceramensis and radiolaria. Early Jurassic Ogena Limestone, pelagic, with ammonites Phylloceras, Psiloceras and Arietites and foraminifera Involutina liassica, Epistomina. Late Jurassic Rumu Fm ~150m red pelagic limestone-marl with manganese deposits and Belemnopsis gerardi, Malayomaorica, Stomiosphaera moluccana and Cadosina fusca. Cretaceous Tobelo Fm deep marine calcilutite with radiolaria, Globotruncana, Heterohelix, etc.. Unconformably overlain by 1300m Miocene Tondo Fm limestone and clastics with oil seeps-asphalt in S Buton (basal limestone latest Oligocene?; JTvG), Pliocene Sampolakosa Fm marls. Late Oligocene collision between Buton Block and SE Sulawesi caused folding-thrusting of Pre-Miocene rocks)

Smith, R.B. (1983)- Sedimentology and tectonics of a Miocene collision complex and overlying late orogenic clastic strata, Buton Island, Eastern Indonesia. Ph.D. Thesis University of California, Santa Cruz, p. 1-254. *(Unpublished)* *(Buton exposes M Miocene collision complex, overlain by clastics derived from erosion of uplifted complex. In Wolio Complex, lower part of ophiolite sequence juxtaposed with Triassic- Upper Eocene or Oligocene sediments in imbricate series of W-dipping thrust sheets with deep water limestones. Age of collision later in Sulawesi East Arm (Late Miocene) than in Buton (M Miocene). Buton- E Sulawesi collision zone evolved from W-dipping subduction zone. M- Late Miocene clastic strata (Tondo Fm) mostly bathyal marine sediments which accumulated in two separate basins. Lasalimu basin formed just E of uplifted ophiolite thrust front, which provided most of detritus to basin, forming coastal fan-deltas, slope and base-of-slope deposits. Langkalome basin turbidites accumulated W of uplifted ophiolite belt. (N.B.: post-orogenic Tondo Fm limestone member contains Spiroclypeus, signifying Early Miocene age?; suggesting collision older than E Miocene?; JTvG))*

Smith, R.B. (1987)- Diachronous Neogene microcontinent collision in Buton and Eastern Sulawesi, Indonesia. Geol. Soc. America (GSA) Ann. Mtg 1987 and Exposition, Abstracts with Programs 19, 7, p. 850. *(Abstract only)*

Smith, R.B. & E.A. Silver (1991)- Geology of a Miocene collision complex Buton, Eastern Indonesia. Geol. Soc. America (GSA) Bull. 103, p. 660-678.
(Buton part of Neogene collision zone along E margin of Sulawesi. Miocene collision of microcontinents with W-dipping subduction zone emplaced Tukang Besi Platform (TBP) against Buton. Buton Wolio collision complex imbricated W-dipping thrust sheets and overturned folds with later steep faults offsetting imbricate

stack and controlling present map patterns. Consists of (1) Turumbia Fm mainly Late Triassic- Late Eocene or Oligocene deep-water limestone in E, interpreted as deep-water facies of W TBP margin; (2) Massive peridotite in W, with full ophiolite succession suggested by clasts in overlying conglomerates; (3) Mukito Fm metabasite and metachert remnants of metamorphic sole at base of ophiolite. Pelitic phyllite and quartzite in NE Buton probably slice of TBP continental basement: similar rocks dredged from NE margin of TBP and also form pre-Mesozoic basement of SP. M-U Miocene Tondo Fm clastics derived from uplift and erosion of Wolio Complex, placing M Miocene upper limit on age of TBP collision. Oblique convergence continued into Late Miocene)

Hall, R., M.G. Audley-Charles, F.T. Banner, S. Hidayat & S.L. Tobing (1988)- The basement rocks of the Halmahera region, eastern Indonesia: a Late Cretaceous-Early Tertiary arc and fore-arc. J. Geol. Soc. London 145, p. 65-84.
(W Halmahera active volcanic arc. E Halmahera basement dismembered ophiolites with slices of Mesozoic and Eocene sediments, unconformably overlain by M Oligocene and younger sediments and volcanics. Mesozoic-Eocene sediments similar to Marianas fore-arc. E Halmahera basement interpreted as pre-Oligocene fore-arc lacking accretionary complex. Mesozoic- Tertiary sediments imbricated with igneous and metamorphic rocks represent deeper parts of fore-arc during Late Eocene plate reorganization. S Bacan basement continental metamorphic rocks associated with deformed ophiolitic complex, different from E Halmahera. Metamorphic rocks interpreted to be part of N Australian continental margin basement, separated from Halmahera by splay of Sorong Fault system. Deformed ophiolite complex of Bacan may represent magmatism in fault zone)

Hall, R., M.G. Audley-Charles, F.T. Banner, S. Hidayat & S.L. Tobing (1988)- Late Palaeogene- Quaternary geology of Halmahera, Eastern Indonesia: initiation of a volcanic island arc. J. Geol. Soc. London 145, p. 577-590.
(Halmahera rel. complete M Oligocene- Recent sedimentary section unconformable on ophiolitic complex, part of Late Cretaceous- E Tertiary forearc. After volcanic arc activity ceased in Eocene, former fore-arc terrane uplifted and eroded in Late Paleogene. Clasts of Eocene reefal limestone with Discocyclina in ?Oligocene- E. Miocene Jawati conglomerate. Widespread Late Oligocene- Miocene carbonates. No evidence of arc volcanism in C Halmahera between Eocene and Pliocene. Oligo-Miocene volcanism in nearby regions interpreted as related to Sorong Fault system. Rapid subsidence in E Pliocene (tied to initiation of subduction of Molucca Sea) lead to basinal marls deposition, followed by siliciclastic turbidites with increasing amounts of calc-alkaline volcanic debris from W Halmahera Pliocene arc. Deformation in Pleistocene at junction of E and W Halmahera. Third Halmahera arc (Quaternary) active in N part of the islands since 1 Ma)

Hall, R., P.D. Ballantyne, A.S. Hakim & G.J. Nichols (1996)- Basement rocks of Halmahera, eastern Indonesia: implications for the early history of the Philippine Sea. In: G.P. & A.C. Salisbury (eds.) Trans. 5th Circum-Pacific Energy and Mineral Resources Conference, Honolulu 1990, Gulf Publishing, Houston, p. 301-317.
(Oldest rocks on Halmahera are 'supra-subduction zone' ophiolites, overlain by Late Cretaceous and Eocene arc volcanics and sediments. Late Cretaceous- Eocene age plutonic rocks intrude ophiolites. Shallow marine Eocene limestones unconformably overlain by Neogene sediments. Halmahera basement many similarities to submarine plateaus and ridges of Philippine Sea and E Philippines basement terranes, suggesting existence of extensive Late Cretaceous and Eocene volcanic arc(?) systems on Mesozoic ophiolitic basement)

Hall, R., M. Fuller, J.R. Ali & C.D. Anderson (1995)- The Philippine Sea plate: magnetism and reconstructions. In: B. Taylor & J.H. Natland (eds.) Active margins and marginal basins: a synthesis of Western Pacific drilling results, American Geophys. Union (AGU) Monogr. 88, p. 371-404.
(online at: http://searg.rhul.ac.uk/pubs/hall_etal_1995%20Philippine%20Sea%20plate%20palaeomagnetism%20AGU%20Monograph.pdf)
(Paleomagnetic results from ocean drilling and from land on Philippine Sea Plate indicate progressive N-ward translation of plate during Tertiary. ODP Leg 126 showed large CW declination shifts of up to -90° since E Oligocene. Similar large declination shifts at land sites at E margin of plate, similar changes in inclination as

ocean drilling sites, and explained as result of entire plate rotation, marginal basin opening, and/or local tectonic deformation at plate edge. Propose plate rotated clockwise since E Tertiary by 5.5° between 0- 5 Ma, 34° between 5- 25 Ma, 50° between 40-50 Ma)

Hall, R. & G.J. Nichols (1990)- Terrane amalgamation in the Philippine Sea margin. Tectonophysics 181, p. 207-222.
(Philippine Sea plate includes plateaus of thickened crust, separated by thinner oceanic crust. Arrival of plateaus at subducting SW margin of Philippine Sea plate caused Philippine Trench to propagate S-ward in increments and caused transfer of terranes to Philippine margin. New data from the Halmahera region indicate plate boundaries strongly influenced by heterogeneous character of Philippine Sea plate. At present the Philippine Trench terminates at oceanic plateau which is structurally continuous with old forearc and ophiolite terrane on Halmahera. Position of this terrane caused Philippine Sea plate- Eurasia convergence to be transferred from subduction at Philippine Trench to Molucca Sea Collision Zone through NE-SW dextral transpressional zone across Halmahera)

Hall, R. & G. Nichols (1991)- Exploration in basins of the western Pacific margin: reducing the risk. In: J.W. Cosgrave & M.E. Jones (eds.) Neotectonics and resources, Belhaven Press, London, p. 243-256.

Zulkarnain (2012)- Across- and along-arc geochemical variations of lava chemistry in the Sangihe arc: various fluid and melt slab fluxes in response to slab temperature. Geochem. Geophys. Geosystems 13, 10, Q10021, p. 1-27.

(online at: http://onlinelibrary.wiley.com/doi/10.1029/2012GC004346/epdf)
(Sangihe oceanic arc N of NE Sulawesi 500km long, with >25 Quaternary volcanoes. Is W half of active arc-arc collision. In S arc, volcanic front lavas enriched in fluid-mobile elements, while rear arc lavas more enriched in melt-mobile elements. Proportion of sediment versus altered oceanic crust in slab component only ~20% but larger than other arcs in W Pacific, suggesting more subduction of thick sediments in narrowing Molucca Sea. Lavas from dormant N Sangihe arc similar to Quaternary rear arc rather than Quaternary volcanic front lavas in S arc, possibly related to advanced collision in N arc that could have slowed subduction)

Hartadi, E.T., R. Mjos, S.I. Midtbo, P.T. Allo, G. Toxopeus, S. Hay, N. Pickard et al. (2013)- Early insights into the exploration of the Halmahera Basin, East Indonesia. Proc. 37th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA13-G-092, p. 1-6.

(On Late Pliocene epithermal vein systems in Toguraci Au-Ag deposit of Gosowong goldfield, N Halmahera. Host rocks bimodal basaltic to andesitic volcanic lavas, volcaniclastics and diorites with zircon U-Pb isotopic ages of ~3.1-3.7 Ma. Epithermal mineralisation dated as 2.8-2.9 Ma)

Milsom, J., R. Hall & T. Padmawidjaja (1996)- Gravity fields in eastern Halmahera and the Bonin Arc; implications for ophiolite origin and emplacement. Tectonics 15, 1, p. 84-93.
(Classic large ophiolite bodies generally associated with large gravity anomalies. No large anomalies in ophiolitic fragmented terranes like E Halmahera-Waigeo terrane. Ophiolites probably Jurassic age and associated with Cretaceous- M Eocene island arc volcanics. Crust at least 20km thick, probably thickening in intra-oceanic island arc. Waigeo also has Oligocene volcanoclastics)

Milsom, J., L. Parson, D. Massom, G. Nichols, N. Sikumbang & B. Dwiyanto (1996)- Tectonics of the Palau-Halmahera- Waigeo triangle. In: G.P. & A.C. Salisbury (eds.) Trans. 5th Circum-Pacific Energy and Mineral Resources Conference, Honolulu 1990, Gulf Publishing, Houston, p. 385-395.
(Region E of Halmahera occupied by number of blocks of thickened island-arc crust and regions of deeper water underlain by oceanic crust. Geological history still obscure. East Philippine Sea Arc formed in Eocene; had E-W strike in Oligocene, now N-S alignment after rotation of Philippine Sea Plate. In earliest Miocene, a second arc terrane, which also included Eocene volcanics, welded onto New Guinea which at that time was 2000km S of present position)

Moore, G.F., D. Kadarisman, C.A. Evans & J.W. Hawkins (1981)- Geology of the Talaud Islands, Molucca Sea collision zone, northeast Indonesia. J. Structural Geol. 3, p. 467-475.
(Talaud Islands at N margin of collision zone between Sangihe and Halmahera island arc systems. Oldest rock units are dismembered ophiolites and Early Miocene(?) tectonic melange with blocks of serpentinite, M Eocene radiolarian chert, etc. Overlain by folded, W-verging M Miocene-Pleistocene marine sediments)

Moore, G.F., D. Kadarisman & Sukamto (1980)- New data on the geology of the Talaud Islands, Molucca Sea. Bull. Geol. Res. Dev. Centre 13, p. 5-12.
(Talaud islands at N end of Molucca Sea with E-dipping slabs of ophiolite in tectonic melange, associated with M Eocene cherts and limestones. Overlain by moderately deformed, very deep marine M Miocene- Pliocene sediments. Talaud ophiolites interpreted as fragments of Eocene or older oceanic crust and mantle, emplaced into forearc terrane in Early Miocene. Talaud Island block uplifted >2000m since Pliocene)

Moore, G.F. & E.A. Silver (1983)- Collision processes in the northern Molucca Sea. In: D.E. Hayes (ed.) The tectonic and geologic evolution of Southeast Asian seas and islands 2, American Geophys. Union (AGU), Geophys. Monograph 27, p. 360-372.
(Collision zone between two facing island arcs. W Mindanao Arc collided in mid-Tertiary with E Mindanao Arc. Thick sediments, presently being deformed in Molucca Sea collision zone, eroded from New Guinea and Halmahera in S and from collision zone in Mindanao. Substantial strike-slip motion during collision. Two new subduction zones at Cotabato and Philippine trenches are propagating S-ward)

Morrice, M.G. (1982)- Mineralogy, petrology and geochemistry of the Sangihe Arc; volcanism accompanying arc- arc collision in the Molucca Sea, Indonesia. Ph.D. Thesis University of California, Santa Cruz, p. 1-363.

Morrice, M.G. & J.B. Gill (1986)- Spatial patterns in the mineralogy of island-arc-magma series-Sangihe-Arc, Indonesia. J. Volcanology Geothermal Res. 29, p. 311-353.
(500km long Sangihe arc is W part of two colliding arcs in NE Indonesia. Andesites dominate. Plagioclase basalts at S volcanic front evolve to two-pyroxene andesites. Augite basalts behind volcanic front and to N where collision more complete, evolve to hornblende andesites. Percentage of mantle fusion highest at S volcanic front)

Morrice, M.G., P.A. Jezek, J.B. Gill, D.J. Whitford & M. Monoarfa (1983)- An introduction to the Sangihe arc: volcanism accompanying arc-arc collision in the Molucca Sea, Indonesia. J. Volcanology Geothermal Res. 19, p. 135-165.
(In Molucca Sea region Sangihe and Halmahera arcs presently colliding (earth's only example of collision between facing volcanic arcs). Collision more advanced in N Molucca Sea where back-arc thrusting occurs along Cotobato and Philippine trenches and volcanic centers are inactive and dissected. Sangihe Arc ~500 km long, from NE tip of Sulawesi to Mindanao, Philippines, with 25 Quaternary volcanic centers. Active volcanic belt 70 km wide, 100-180 km above top of W-dipping Benioff zone. Rockes range from basalt to rhyolite, mainly andesites. Tholeiitic suites confined to S volcanic front. Calc-alkaline suites throughout arc. S to N increase in LIL-elements without corresponding changes in Sr-isotopes interpreted as decreasing partial melting N-ward)

Morris, J.D., P.A. Jezek, S.R. Hart & J.B. Gill (1983)- The Halmahera island arc, Molucca Sea collision zone, Indonesia: a geochemical survey. In: D.E. Hayes (ed.) The tectonic and geologic evolution of Southeast Asian seas and islands, 2, American Geophys. Union (AGU), Geophys. Monograph 27, p. 373-387.
(W Halmahera volcanic arc above 45° E-dipping Benioff zone, present down to 230 km. Three regions with distinct chemistry and tectonic setting. Most volcanoes part of calc-alkaline oceanic segment. Continental suite on Bacan reflects intersection of oceanic arc with continental fragment. Origin of alkaline rocks on inactive volcanic islands along Sorong Fault zone unclear)

Nichols, G.S. & R. Hall (1991)- Basin formation and Neogene sedimentation in a backarc setting, Halmahera, eastern Indonesia. Marine Petroleum Geol. 8, p. 50-61.

(Halmahera Basin formed by subsidence of thickened crust of imbricated Mesozoic-Paleogene arc and ophiolite rocks. In Miocene basement complex formed thickened crust on which reef and reef-associated sediments were deposited, similar to Philippine Sea Plate plateaux and ridges. Late Miocene convergence between Philippine Sea Plate- Eurasian margin resulted in formation of Halmahera Trench to W. Subduction of Molucca Sea Plate at trench caused development of volcanic island arc. Subsidence in back-arc area produced sedimentary basin filled by clastics eroded from arc and uplifted basement and cover rocks. Basin asymmetric, thickest sediments on W side, against volcanic arc. Halmahera Basin modified by Plio-Pleistocene E-W compression as Molucca Sea Plate was eliminated by subduction).

Nichols, G., R. Hall, J. Milsom, D. Masson, L. Parson, N. Sikumbang, B. Dwiyanto & H. Kallagher (1990)- The southern termination of the Philippine Trench. Tectonophysics 183, p. 289-303.
(Philippine Trench in process of propagating S and some of ESE-WNW convergence is transferred via broad NE-SW zone of dextral strike-slip across N Halmahera into Molucca Sea Collision Zone. E Halmahera-Waigeo Ophiolite Terrane area of shallow water and islands underlain by ophiolitic basement between Halmahera and Sorong Fault Zone. Halmahera is in diffuse boundary zone at margin of Philippine Sea Plate)

Nichols, G., Kusnama & R. Hall (1991)- Sandstones of arc and ophiolite provenance in a backarc basin, Halmahera, eastern Indonesia. In: A.C. Morton, S.P. Todd & P.D.W. Haughton (eds.) Developments in sedimentary provenance studies, Geol. Soc., London, Spec. Publ. 57, p. 291-303.
(Late Neogene backarc basin on Halmahera distinctive detrital sandstones mineral assemblages. Quartz extremely rare, indicating no input from continental sources. Two provenance areas: volcanics in W half of basin and black sands of ultrabasic origin interbedded with carbonate mudstones in E of basin. These reflect nature of terrains which bordered Halmahera Basin)

Islands mainly composed of igneous core, of mainly gabbros and peridotites, with thin sediment cover (probably Mesozoic radiolarian chert, breccias, overlain by presumably Tertiary unfossiliferous sandstones and marls). With 1:200,000 map)

Ryan, M., H. Butcher, T. Halvorsen, L.W. Kuilman, J. Demichelis, Sayentika, A. Jansson et al. (2012)- An early look at the hydrocarbon prospectivity of the Halmahera Basin, Eastern Indonesia. Proc. 36th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA12-G-078, p. 1-14.
(On Halmahera II PSC in Halmahera frontier basin acreage. Prospective plays Oligocene/Miocene carbonate reefal buildups and Miocene re-deposited carbonates. Potential source rocks source rock marine Miocene Klamogun and Klasafet-equivalent formations (but see also Yustiana et al. 2016))

Sartono, S. & S. Hadiwisastra (1989)- Ophiolitic melange in Gebe Island and its olistostromal origin. In: B. Situmorang (ed.) Proc. 6th Regional Conf. Geology mineral hydrocarbon resources of Southeast Asia (GEOSEA VI), Jakarta 1987, IAGI, p. 157-169.
(Gebe Island between Halmahera and Waigeo with nickel-chromite deposits. Chaotic basement complex overlain by U Miocene-Pliocene bioclastic limestones. Basement probably olistostrome, with ultrabasic and metamorphic clasts and probably Eocene- E Miocene age)

Setyanta, B. & I. Setiadi (2011)- Model struktur subduksi kerak di perairan Laut Maluku dan vukanisme berdasarkan analisis gaya berat dan kegempaan. J. Sumber Daya Geologi 21, 4, p. 213-223.
(online at: http://jgsm.geologi.esdm.go.id/index.php/JGSM/article/view/148/144)
('Model of crustal subduction structure in Molucca Sea waters and volcanism by analysis of gravity and seismicity'. N-S Bouguer anomalies of -100 to 260 mGal. Gravity modelling indicates subducting slab under Halmahera steeply dipping E, while in W part (below N arm of Sulawesi) it is not visible)

Silitonga, D. (2013)- Characteristics of Gosowong goldfields epithermal deposits. Proc. Indonesian Soc. Econ. Geol. (MGEI) Annual Conv. 2013, Papua & Maluku Resources, Bali, p. 115-124.

Silitonga, P.H., H. Pudjowalujo & H. Mollat (1981)- Geological reconnaissance and mineral prospecting on Bacan Island (Moluccas, Indonesia). In: A.J. Barber & S. Wiryosujano (eds.) The geology and tectonics of eastern Indonesia, Geol. Res. Dev. Centre (GRDC), Bandung, Spec. Publ. 2, p. 373-381.
(Bacan Island oldest rocks intensely deformed mica schists and amphibolites and associated ultrabasic rocks of unknown age and NNE-SSW foliation. Oldest dated rocks probably Late Oligocene- Early Miocene age submarine andesites intruded by granodiorites and with intercalated coral limestones. Volcanic series overlain byE-M Miocene marine clastics with common volcanic detritus, overlain by Late Tertiary- Quaternary Young volcanics. Recent coral reefs raised to 700m above sea level)

Silver, E.A. & J.C. Moore (1978)- The Molucca Sea collision zone, Indonesia. J. Geophysical Research 83, B4, p. 1681-1691.
(Same as Silver & Moore 1981. N- trending Sangihe and Halmahera volcanic arcs face each other and underlain by opposing Benioff zones. Talaud-Mayu Ridge between arcs consists exclusively of deformed rocks, and underlain by at least 8-10 km of low-density material. Length of lithosphere subducted by colliding arcs >1000 km (length of Benioff zones). Obduction of melange and ophiolite belts against island arcs or continental margins. Central part of mostly submarine Talaud-Mayu ridge 1-3 km higher than flanking troughs. Two opposing vergence directions in rocks of collision complex: (1) during subduction, verging away from arcs, (2) during present phase of collision, verging towards arcs)

Silver, E.A. & J.C. Moore (1981)- The Molucca Sea collision zone. In: A.J. Barber & S. Wiryosujono (eds.) The geology and tectonics of Eastern Indonesia, Proc. CCOP-IOC SEATAR Working Group Mtg., Bandung 1979, Geol. Res. Dev. Centre (GRDC), Bandung, Spec. Publ. 2, p. 327-340.
(Scripps 1977 seismic profiles across Molucca Sea. Molucca Sea zone of crustal collision bordered by N trending Sangihe and Halmahera volcanic arc underlain by opposite-dipping Benioff zones. Length of Benioff zones suggest at least 1000km of subducted lithosphere. At least 8-10 km of low-density collisional melange material, now exposed on Talaud, Mayu, Tifoe islands)

Sodik, A., M.G. Rukmiati & J. Purnomo (1993)- Hydrocarbon potential of frontier Weda Basin, South East Halmahera. Proc. 22nd Ann. Conv. Indon. Assoc. Geol. (IAGI), Bandung, 2, p. 653-663.
(Southernmost Halmahera metamorphic terrane is microcontinent derived from Irian Jaya (Kemum?), moved W along Sorong FZ. E arms of Halmahera are Jurassic-age ophiolite terrane. Up to 5000m of sediment in Weda basin, offshore SE Halmahera, with Miocene carbonates as main potential play)

Soeria Atmadja, R. (1981)- Ophiolites in the Halmahera paired belts, East Indonesia. In: A.J. Barber & S. Wiryosujano (eds.) The geology and tectonics of eastern Indonesia. Geol. Res. Dev. Centre Indonesia, Spec. Publ. 2, p. 363-372.
(Halmahera is connected double arc. N and S arms are W volcanic arc, mainly Quaternary volcanics, Neogene marine sediments and Oligo-Miocene volcanics. NE and SE arms large ophiolite belt (subduction zone ophiolite) with ultramafic rocks imbricated with Mesozoic deep water sediments and E Tertiary rocks)

Yasin, A. (1980)- Geologic map of the Bacan Quadrangle, North Maluku, 1:250,000. Geol. Res. Dev. Centre (GRDC), Bandung, 9p.
(Bacan Island off S Halmahera with core of thick Sibela Fm metamorphics with NW-SE and W-E trending foliation. Unconformably overlain by Late Oligocene- earliest Miocene Bacan Fm volcanics and clastics and later Miocene- Pliocene clastics- volcanoclastics)

Yustiana, F., C. Zwach, D. Rahmalia & P.T. Allo (2016)- Halmahera Basin, Eastern Indonesia- hydrocarbon prospectivity in a frontier basin. Proc. IPA 2016 Technical Symposium, Indonesia exploration: where from- where to, Indon. Petroleum Assoc. (IPA), Jakarta, 34-TS-16, p. 1-23.
(Halmahera II PSC SE of Halmahera is in Tertiary deep water, undrilled frontier basin, now considered area with very high subsurface risk and lack of follow-up prospectivity. Basement most likely ophiolites and volcanics. Potential Miocene carbonate buildups now interpreted to be Oligocene thrust complexes. Clastic reservoir provenance likely dominated by volcanic rocks. No indications of active hydrocarbon system)

Zhang, Q., F. Guo, L. Zhao & Y. Wu (2017)- Geodynamics of divergent double subduction: 3-D numerical modeling of a Cenozoic example in the Molucca Sea region, Indonesia. J. Geophysical Research, Solid Earth, 122, 5, p. 3977-3998.
(Molucca Sea subduction zone in NE Indonesia in SE Asia is unique Cenozoic example of 'divergent double subduction' (DDS), under Halmahera and Sangihe arcs. Asymmetrical shape. DDS probably associated with closure of narrow and short oceanic plate; large-scale double subduction is rare in nature)

VI.2. Banggai, Sula, Taliabu, Obi

Agustiyanto, D.A. (1996)- The geology and tectonic evolution of the Obi region, Eastern Indonesia. M. Phil. Thesis, University of London, p. 1-220. *(Unpublished)*
(Obi located within strands of Sorong Fault system at Australian-Philippine Sea plate boundary. Oldest rocks metamorphic complex of phyllites, schists and gneisses, probably Paleozoic in age, in greenschist- amphibolite facies. Overlain by Triassic and Jurassic micaceous sandstones and black shales, considered derived from Australian continental margin. Ophiolitic rocks, of supposed Jurassic age, form basement of most of Obi region, are unconformably overlain by Cretaceous volcaniclastic rocks, limestones and mudstones. Juxtaposition of the ophiolitic and continental rocks in south Obi probably in Late Neogene)

Agustiyanto, D.A. (1998)- Geology of the Obi islands, Eastern Indonesia. J. Geologi Sumberdaya Mineral, 8, 81, p. 2-9.
(Obi islands consist of rocks from Australian (SW) and Philippine Sea (N)plates, juxtaposed in SW part of Obi Majora (in Oligocene or later?). Oldest rocks on Obi island Paleozoic or older 'Australian' Tapas metamorphic complex, regional metamorphic phyllites, mica- schists and gneisses in greenschist to amphibolite facies. Overlain by Triassic- Jurassic Soligi Fm (with Jurassic Pentacrinus) and Kumumu Fms micaceous sandstones and black shales (with Jurassic ammonites in float; Wanner 1913, M-U Jurassic palynomorphs). Most of Obi is 'Philippine Sea' plate with basement of?Jurassic ophiolite, unconformably overlain by U Cretaceous Leleobasso Fm deep water volcanoclastics, limestones and mudstones and Oligocene Anggai River Fm volcanoclastics. Unconformably overlain by E-M Fluk Fm limestone and unconformably overlain by Guyuti Fm M-L Miocene clastics and Woi Fm volcanics and clastics)

Ali, J.R. & R. Hall (1995)- Evolution of the boundary between the Philippine Sea plate and Australia: paleomagnetic evidence from eastern Indonesia. Tectonophysics 251, p. 251-275.
(Paleomagnetic data from Coniacian-Santonian pelagic limestones on Taliabu suggest paleolatitude at 19°± 6°, similar to Misool, suggesting Sula/Taliabu and Misool part of single microcontinent, >10° farther N than expected if attached to Australia, and implying region separated from Australia before Late Cretaceous)

Ali, J.R., R. Hall & S.J. Baker (2001)- Palaeomagnetic data from a Mesozoic Philippine Sea Plate ophiolite on Obi Island, Eastern Indonesia. J. Asian Earth Sci. 19, p. 535-546.
(Paleomag of Jurassic(?) age Halmahera ophiolite exposed on SW Obi Island suggest position close to equator in middle Mesozoic. K-Ar ages of ophiolite 96±10 Ma and 103±13 Ma regarded as minimum ages. Diorite intrusions Late Cretaceous ages)

Amiruddin (2000)- Peraluminous and metaluminous Permian-Triassic granitoids of the Banggai-Sula microcontinent and the Northern Australia continent in the Bird Head Papua. J. Sumber Daya Geologi 10, 110, p. 2-15.
(Permian- E Triassic granites on Banggai, Obi and Birds Head. Banggai granite (~225-245 Ma; Triassic) on Taliabu intruded into Carboniferous (~305 Ma) schists, gneiss amphibolite. Anggi granite (~225-295 Ma) in Kemum Terrane metasediments (metamorphosed at 222-258 Ma; Late Permian-Triassic. Netoni granite (225-245; M-L Triassic) in Sorong fault zone of Birds Head intruded low-middle metamorphic rocks. Banggai and Anggi granites mostly S-type, Netoni I-type. All are peraluminous and metaluminous and could be tin granites. Plutons part of magmatic arc extending from E Australia, PNG, W Papua to Banggai-Sula Archipelago)

Boehm, G. (1904)- Die Sudkusten der Sula-Inseln Taliabu und Mangoli. I. Grenzschichten zwischen Jura und Kreide. Palaeontographica, Suppl. IV, Beitrage Geologie Niederlandisch-Indien 1, p. 1-46.
('The South coast of the Sula islands Taliabu and Mangoli: 1- Transitional beds between Jurassic and Cretaceous'. First systematic descriptions of rich Sula islands ammonite-dominated Jurassic- Cretaceous macrofaunas. Incl. ammonites (Hoplites spp., Himalayites, Phylloceras strigile) and bivalves (Mytilus, Nucula). Noticed great similarities with 'Spiti-Fauna' Himalayan assemblages)

Panuju (2011)- Pre-Tertiary nannoplankton biostratigraphy of Bobong, Buya and Tanamu Formations, Banggai-Sula basin. Proc. Joint 36th HAGI and 40th IAGI Ann. Conv., Makassar, JCM2011-053, 12p.
(Nannoplankton from three M Jurassic- Cretaceous outcrop sections of Sula islands (no locality details), each through different formations. Bobong Fm contains zone NJ9 (Bajocian, M Jurassic; with Watznaueria brittanica, Diductius constans). Buya Fm zone NJ17 (Tithonian, Late Jurassic, with Zeugrhabdotus embergeri at bottom, Stepanolithion bigotii at top). Tanamu Fm zones CC13-CC17 (Coniacian- Campanian, Late Cretaceous, with Marthasterites furcatus at bottom, Quadrum gartneri at top))

Panuju, Irwansyah & E.B. Lelono (2011)- The Jurassic- Cretaceous paleogeography of the Sula area, North Maluku. Lemigas Scientific Contr. 34, 1, p. 67-83.
(7 depositional sequences in Jurassic-Cretaceous succession of Sula area. Sequences 1 (Bobong Fm), 2, 3 and 4 (Buya Fm) of Jurassic age, sequences 5, 6 and 7 (Buya Fm) attributed to Cretaceous. General deepening of

depositional environment to North. Deepest environment is outer neritic (100m-200m). Jurassic-Cretaceous depocenter in N part of study area)

Permana, H. (1987)- Ofiolit daerah Akelamo, Pulau Obi, Maluku Utara. J. Riset Geologi Pertambangan (LIPI) 8, 1, p. 13-24.
('Ophiolite in the Akelamo area, Obi Island, North Moluccas'. Melange complex of SW Obi (presumably post-Jurassic), with basic-ultrabasic rocks (peridotite, gabbro with dikes of plagiogranite and basalt), crystalline limestone, etc. Overlain by Oligocene volcanoclastics and younger sediments)

Pertamina/BPPKA (1996)- Petroleum geology of Indonesian basins, VI-IX Eastern Indonesian Basins, VI-Banggai, Jakarta, p. 1-24.

Pessagno, E.A. & D. Meyerhoff Hull (2002)- Upper Jurassic (Oxfordian) radiolaria from the Sula Islands (East Indies): their taxonomic, biostratigraphic, chronostratigraphic, and paleobiogeographic significance. Micropaleontology 48, 3, p. 229-256.
(L-M Oxfordian radiolarians from Buya Fm mudstones of Mangole Island with common Praeparvicingula and rare pantanelliids and association with Austral ammonites suggest assemblage from outside Central Tethyan Pantanellidae realm, but belongs to Northern Austral Province Parvicingula- Praeparvicingula Realm (>30°S paleolatitude), in keeping with Gondwana origin of Sula. New species Bigrumpta moluccaenis, Crucella capaluluensis, C. hamiltoni, C. taliabuensis, C. westermanni, Grumpta australis, Acanthocircus tansinhoki, A. waigaloensis, etc.)

Pigram, C.J., Surono & J.B. Supandjono (1985)- Geology and regional significance of the Sula Platform, East Indonesia. Bull. Geol. Res. Dev. Centre (GRDC), Bandung, 11, p. 1-13.
(Sula Platform basement Paleozoic slates-schists (K-Ar age 305 Ma) and Late Permian-Triassic granitoids-acid volcanics. Unconformably overlain by E Jurassic non-marine Kabauw Fm clastics, grading upward into fossiliferous Buya Fm M Jurassic- E Cretaceous bathyal black shale, overlain by Late Cretaceous Tanamu Fm calcilutites. Unconformably overlain by Miocene shallow marine limestones. Sula stratigraphy correlates poorly with W Irian Jaya stratigraphy, but most similar to central PNG. May be detached from PNG in Jurassic. Unlikely to be transported to E Indonesia by transcurrent faults, which in PNG did not develop before Late Oligocene)

Pigram, C.J., Surono & J.B. Supandjono (1985)- Origin of the Sula Platform, Eastern Indonesia. Geology 13, p. 246-248.
(Similar to paper above. Sula Platform stratigraphy closer to Central PNG between 141°-145° than to W New Guinea, implying E to W displacement of >2500 km. Sula stratigraphy characterized by Paleozoic low-grade metamorphics, Permo-Triassic granitoids and rel. complete marine Jurassic section, similar to PNG. Cretaceous on Sula is bathyal Late Cretaceous carbonates only, different from PNG which has more complete Cretaceous section, suggesting separation of Sula Platform in Early Cretaceous?)

Rahmalia, D., P.T. Allo, C. Zwach, R. Heggland & S.I. Midtbo (2017)- Hydrocarbon prospectivity in the South Obi Basin. Proc. 41st Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA17-119-G, 15p.
(Seismic data in deepwater basin between Obi and Bacan/ S Halmahera, formed as pull-apart basin along Sorong fault zone. Indications of Miocene Kais carbonate buildups and potential gas chimneys)

Rudyawan, A. & R. Hall (2012)- Structural reassessment of the South Banggai-Sula area: no Sorong fault zone. Proc. 36th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA12-G-030, p. 1-17.
(New seismic data suggests strands of Sorong Fault can be traced from New Guinea towards Sula Islands, but no through-going Sorong Fault Zone traceable to S of Banggai-Sula block. Absence of through-going strike-slip fault zone along S Taliabu Shelf indicates Banggai-Sula block not transported to W by Sorong Fault Zone)

Rutten, L.M.R. (1927)- De noordelijke Molukken en de Radja-Ampat groep. In: L.M.R. Rutten (1927) Voordrachten over de geologie van Nederlandsch Indie, Wolters, Groningen, p. 761-782.

(Geologic map of Manggole, Sanana and E Talibu islands (E part of Banggai Sula islands). Buya Fm M-L Jurassic rich in macrofossils: ammonites (Blanfordiceras, Himalayites, Stephanoceras, Macrocephalites), belemnites (Belemnopsis stolleyi, B. mangolensis), bivalves (Inoceramus, Malayomaorica))

Van Nouhuijs, J.W. (1910)- Bijdrage tot de kennis van het eiland Taliaboe der Soela groep (Moluksche Zee). Tijdschrift Kon. Nederlands Aardrijkskundig Genootschap (2), 27, p. 945-976 and p. 1173-1196.
('Contribution to the knowledge of Taliabu island of the Sula Group'. Report on first collections of famous Jurassic ammonites and belemnites in 1900 (with Boehm) and 1904, by navy officer Van Nouhuijs. Fossils from folded dark shales underlain by crystalline schist. Including famous Keeuw locality at Wai Miha River, described by Boehm (1912))

Walpersdorf, A., C. Vigny, P. Manurung, C. Subaraya & S. Sutisna (1998)- Determining the Sula block kinematics in the triple junction area in Indonesia by GPS. Geophysical J. Int. 135, p. 351-361.
(Triple junction of three major plate boundaries (Australia- Eurasia- Philippines) is transition zone that includes Sula domain, which shows clockwise rotation)

Wanner, J. (1913)- Zur Geologie der Inseln Obimajora und Halmahera in den Molukken. Neues Jahrbuch Mineral. Geol. Palaontologie, Beilage Band 36, p. 560-585.
('On the geology of islands Obi Besar and Halmahera in the Moluccas' Along Akelamo River of SW Obi: (1) serpentinized peridotite, (2) Pliocene marine marls and (3) black shales with concretions with M Jurassic ammonites Phylloceras, Stephanoceras and Macrocephalites, similar to 'Coronatenschichten' of Sula. E-M Miocene limestone with Miogypsina and Lepidocyclina near S coast near Ngutenute. Also andesitic volcanics, etc. Young raised coral reef terraces up to 320m elevation along S coast)

Watkinson, I.M., R. Hall & F. Ferdian (2011)- Tectonic re-interpretation of the Banggai-Sula-Molucca Sea margin, Indonesia. In: R. Hall, M.A. Cottam & M.E.J. Wilson (eds.) The SE Asian gateway: history and tectonics of Australia-Asia collision, Geol. Soc. London, Spec. Publ. 355, p. 203-224.
(New bathymetric and seismic data from area N of Banggai-Sula Islands provide new insight into boundary between E Sulawesi ophiolite, Banggai-Sula microcontinent and Molucca Sea collision zone. Previously interpreted major faults such as Sula Thrust and N Sula-Sorong Fault, are not seen. Gently dipping strata of Banggai-Sula microcontinent margin can be traced N-wards beneath younger rocks)

Westermann, G.E.G. & J.H. Callomon (1988)- The Macrocephalitinae and associated Bathonian and early Callovian (Jurassic) ammonoids of the Sula islands and New Guinea. Palaeontographica A, 203, p. 1-90.
(Five Bathonian- Early Callovian ammonite assemblages on S Taliabu. Also from Bathonian at PNG Strickland River. East Indian faunas dominated by Macrocephalitidae, many of which are species unknown outside Indonesia- New Guinea (one other SW Pacific occurrence in New Zealand). Because of high endemicity at species level in Macrocephalitinae and at genus level in Satoceras and Irianites, E Indonesia and PNG may be considered as separate ammonite faunal province or subprovince, perhaps part of Maorian/SW Pacific Province during Late Bajocian- E Callovian. Diversity and compositions of ammonite faunas suggest Sula was in warmer waters than Birds Head Peninsula)

Westermann, G.E.G., T. Sato & S.K. Skwarko (1978)- Brief report on the Jurassic biostratigraphy of the Sula Islands, Indonesia. Newsletters Stratigraphy 7, 2, p. 96-101.
(Classic ammonite localities on Taliabu and Mangole reexamined. U Toarcian sst with Hammatoceras overlain by thick Bajocian micaceous marly shales (Fontannesia, etc.). No evidence for Aalenian. Overlying thick marly claystones with E Callovian 'Keeuw fauna' (Macrocephalites, etc.) and 'Wai Galo fauna' with E-M Oxfordian ammonite assemblages (Mayaitidae, Perisphinctes, etc.). No new evidence for Bathonian or higher Callovian. Thick Kimmeridgian-M Tithonian argillaceous sequence in belemnite-bivalve facies (Belemnopsis, Inoceramus, Malayomaorica). Upper Tithonian claystones again rich ammonite fauna (Haplophylloceras, Blanfordiceras, etc.))

(Brief review, showing highly variable porosity and TOC in Triassic Kanikeh Fm outcrop samples)

Al-Shaibani, S. (1983)- The micropalaeontology of the Middle Triassic to Upper Miocene sediments of Seram, Eastern Indonesia. Ph.D. Thesis Imperial College, University of London, p. 1-469.
(online at: https://spiral.imperial.ac.uk/handle/10044/1/36159)
(Planktonic foraminifera of Nief Beds indicate deposition during Cretaceous, Paleocene, Eocene and Miocene in deep bathyal environment. Corroded radiolaria in U Jurassic- Lower Cretaceous part of Nief Beds indicate deposition close to silica compensation depth at ~4000m. Fine grain-size and radiolaria-dominated microfauna of Saman Saman Lst indicate deposition in very deep marine water. Microfaunas of Late Triassic Asinepe Lst reveal deposition during Norian in reefal- sublagoonal environment)

Al-Shaibani, S., D.J. Carter & L. Zaninetti (1983)- Geological and micropaleontological investigations in Upper Triassic (Asinepe Limestones) of Seram, Outer Banda Arc, Indonesia. Archives Sciences Geneve 36, 2, p. 301-316.
(Foraminifera from U Triassic Asinepe Fm tropical-reefal carbonates of Seram show Norian- Rhaetian age. Two distinct foram facies associations: (1) muddy lagoonal facies dominated by Involutinidae, with Triasina hantkeni, Aulatortus spp., etc. and (2) near-reefal facies dominated by porcellaneous forams. No location maps, stratigraphy, etc.)

Al-Shaibani, S., D.J. Carter & L. Zaninetti (1984)- Microfaunes associees aux Involudinidae et aux Milioporidae dans le Trias superieur (Rhetien) de Seram, Indonesie: precisions stratigraphiques et paleoecologie. Archives Sciences Geneve 37, 3, p. 297-313.
(Upper Triassic microfaunas from Asinepe Fm reefal and lagoonal platform limestone, Seram with Rhaetian index foram Triasina hantkeni. Many similarities with U Triassic Tethyan faunas in Europe and Asia)

Aquantino, S., N. Nastiti & A.S. Dradjat (2012)- Penggunaan metoda "the look ahead VSP survey" untuk pencitraan target Formasi di bawa mata bor pada sumur pemboran eksplorasi Lofin 1. Proc. 41st Ann. Conv. Indon. Assoc. Geol. (IAGI), Yogyakarta, 2012-E-30, 5p.
('The use of the "look ahead VSP survey" method for imaging targets during drilling of exploration well Lofin 1'. Lofin-1 exploration well ~70km W of Oseil 2. Target Manusela Lst deeper than pre-drill predictions;not reached at TD of 10957' (in Upper Nief Fm). Look-ahead VSP used to help predict target depths (Lofin 1 ST penetrated ~500' of gas-oil bearing fractured Manusela Fm limestone below ~14000'; JTvG))

Audley-Charles, M.G. & D.J. Carter (1977)- Interpretation of a regional seismic line from Misool to Seram: implications for regional structure and petroleum exploration. Proc. 6th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 2, p. 3-12. *(also in Oil and Gas Journal 23, 1, p. 20-23)*

(Misool to Seram regional seismic shows imbricate zone at boundary of Seram island arc with New Guinea continental shelf. S wall of Seram Trough is like N wall of Timor Trough, interpreted as foothills-type fold belt. This may be regarded as an A-zone (Bally, 1975), representing margin between Banda Arc developing fold belt and Australian craton. Benioff subduction zone interpreted between non-volcanic Outer Banda arc and volcanic Inner Arc. A- and B-zones can be traced around Banda Arcs from Seram to Timor and beyond)

Audley-Charles, M.G., D.J. Carter, A.J. Barber, M.S. Norvick & S. Tjokrosapoetro (1979)- Reinterpretation of the geology of Seram: implications for the Banda arcs and northern Australia. J. Geol. Soc. London 136, p. 547-568. *(also in: Geology and Tectonics of eastern Indonesia, GRDC Spec. Publ. 2, 1981, p. 217-237).*
(online at: http://searg.rhul.ac.uk/pubs/audley-charles_etal_1979_seram.pdf)
(Remarkable similarities between Mesozoic-Miocene deep-water 'para-autochthonous' and shallow water 'allochthonous' successions of Seram and Timor. Triassic limestones in 'Australian facies' mostly planktonic facies Saman Saman Lst in 'para-autochthonous', structurally overlain by 'Asian facies'Asinepe Lst in 'allochthonous')

Bachri, S. (2011)- Tectonostratigraphy and structures of Eastern Seram. J. Geologi Indonesia 6, 2, p. 85-93.
(online at: www.bgl.esdm.go.id/publication/index.php/dir/article_detail/305)
(Seram geology re-interpreted in E Timor-analog tectonic complexes. Most of E Seram is 'Para-autochthonous complex', with Permian Kobipoto metamorphics, overlain by Triassic-Jurassic Kanikeh Fm flysch and age-equivalent Manusela Fm massive limestone, overlain by Cretaceous- Miocene pelagic deposits. 'Allochthonous' overthrusted sequence of ultrabasic rocks comparable to Timor Banda allochton (called Permian age in text, Jurassic-Cretaceous in Fig. 3; JTvG). Salas Complex is M Miocene- M Pliocene deep water olistostrome, similar to Timor Bobonaro Complex. Thrusting Neogene age and verging to NE)

Henny, G. & L.J. Toxopeus (1922)- Eerste verslagen der Boeroe-expeditie. Tijdschrift Kon. Nederlands Aardrijkskundig Genootschap 39, p. 42-64.

('First reports of the Buru Expedition'. Extract of Henny (1922) on travel, geological and biological observations during 1921 SW Buru Expedition. Not much detail on stratigraphy/ fossils. Interesting find of white Nummulites-Discocyclina limestone N of Wai Ekin, not reported on later GRDC geologic maps)

Hill, K.C. (2005)- Tectonics and regional structure of Seram and the Banda Arc. Proc. 30th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 559-578.
(Tectonic reconstruction assuming Permian age of Banda Sea oceanic crust. Suggests Seram Triassic Kanikeh Fm flysch was sourced from E (New Guinea) (Conflicts with pre-WWII Rutten field observations suggesting Triassic more sandy and coarser to W, and derived from metamorphic/ volcanic arc terrane; JTvG))

Hill, K.C. (2012)- Tectonic and regional structure of Seram and the Banda Arc. Berita Sedimentologi 23, p. 5-16.
(online at: www.iagi.or.id/fosi/)
(Same paper as above)

Honthaas, C., R.C. Maury, B. Priadi, H. Bellon & J. Cotten (1999)- The Plio-Quaternary Ambon arc, Eastern Indonesia. Tectonophysics 301, 3-4, p. 261-281.
(Pliocene- Quaternary N Banda Arc at Ambon, S Seram, Kelang, Haruju, Saparua, Ambelau and Banda Api with low-K arc volcanics, but on Ambon also high-K cordierite dacites-granites, probably derived from low-K magmas with massive assimilation of overlying Seram-Ambon continental crust. Two magmatic pulses: 5- 3.2 Ma and 2.3- 1 Ma. Active subduction of New Guinea crust below Ambon-Seram supported by volcanism, earthquakes, etc., but N Banda slab not connected to S Banda Arc Wetar-Manuk segment)

Hummel, K. (1923)- Geologische Ergebnisse der Reisen K. Deninger's in den Molukken. II. Die Oxford-Tuffite der Insel Buru und ihre Fauna. Palaeontographica Suppl. IV, 4, p. 113-184.
(online at: http://sammlungen.ub.uni-frankfurt.de/botanik/periodical/pageview/4499569)
('Geological results of K. Deniger's travels in the Moluccas, 2: The Oxfordian tuffites of Buru islands and its fauna'. Descriptions of Late Jurassic fossils from 9 localities at SW coast and NW Buru, collected by Boehm and Deninger in 1907, 1912. These are from reddish 'Mefa Beds tuffites', 200-300m thick?, most fossiliferous near top. Almost everywhere overlain by thick, latest Jurassic- Cretaceous deep water Buru Limestone, and probably directly overlying U Triassic Lovcenipora limestone or bituminous shale. Fossils mainly ammonites (Phylloceras spp., Harpoceras, Oppelia, Perisphinctes), rare belemnites (to be described by Stolley), thick-walled bivalves (Opis, Pecten, Alectryonia; no Inoceramus), ribbed brachiopods (Rhynchonella spp.), etc.. Age believed to be E Oxfordian. Facies rel. shallow marine compared to generally bathyal facies of age-equivalent rocks in Moluccas (Sula, Seram). Faunal affinities with Mediterranean-Caucasian Realm)

Idrus, A., Fadlin, I. Setiawan, S. Abdullah & B. Smith (2012)- Preliminary study on primary gold mineralization in Buru Island, Moluccas Province, Indonesia. In: N.I. Basuki (ed.) Proc. Banda and Eastern Sunda arcs, Indonesian Soc. Econ. Geol. (MGEI) Ann. Conv. 2012, Malang, p. 233-242.
(Gold nuggets from quartz vein mineralization hosted by mica schist of Carboniferous-Permian Wahlua Metamorphic Complex, discovered in 2012 around Gunung Botak, E Buru Island. Two types: (1) early quartz veins, discontinous and low in gold; (2) Quartz veins in 'mineralized zone' ~100m wide and ~1000m long. Ore mineralization characterized by pyrite, native gold, pyrrhotite and arsenopyrite. Mineralizing hydrothermal fluid CO2-rich, Temperature 300-400 ºC and low salinity (0.36- 0.54% NaCl eq). Mineralization in Buru Island meets characteristics of 'mesothermal' gold deposit type or 'orogenic' gold deposit type)

Idrus, A., S. Prihatmoko, Ernowo & Franklin (2013)- Update of metamorphic rock-hosted gold mineralization in Buru Island, Moluccas Province. In: Proc. Papua and Maluku Resources, Indonesian Soc. Econ. Geol. (MGEI) Ann. Conv., Bali, p. 89-98.

Idrus, A., S. Prihatmoko, H.G. Hartono, Fadlin, Ernowo, Moetamar & I. Setiawan (2014)- Some key features and possible origin of the metamorphic rock-hosted gold mineralization in Buru Island, Indonesia. Indonesian J. Geoscience 1, 1, p. 9-19.
(online at: http://ijog.bgl.esdm.go.id/index.php/IJOG/article/view/172/172)

(Buru primary gold deposits mainly in 2 localities Gogorea and Gunung Botak in E half of island, Two types of gold-bearing quartz veins in micaschists of U Carboniferous- Lw Permian Wahlua Fm metamorphic complex (similar to Bombana in Pompangea complex, E Sulawesi).Mineralization may be controlled by N-S of NE-SW trending strike-slip faults)

(SW Seram and Ambon ultramafics obduction minimum age ~4.4 Ma. Obducted oceanic lithosphere was created at ~14.5 Ma. Obduction probably simultaneous with strong anticlockwise rotation of Seram)

Linthout, K., H. Helmers & P.A.M. Andriessen (1991)- Dextral strike-slip in Central Seram and 3-4.5 Ma Rb/Sr ages in pre-Triassic metamorphics related to Early Pliocene counterclockwise rotation of the Buru-Seram microplate (E. Indonesia). J. Southeast Asian Earth Sci. 6, p. 335-342.
(Major WNW trending right-lateral strike slip fault in SW Seram. Pre-Triassic metamorphics show Pliocene radiometric ages, possibly resetting from ophiolite obduction. Structural analyses suggest 45° counter clockwise rotation and radiometric age resetting between 4.5- 3 Ma, and final ~30° rotation in last 3 Ma)

Linthout, K., H. Helmers, J. Sopaheluwakan & E. Surya Nila (1989)- Metamorphic complexes in Buru and Seram, northern Banda Arc. In: J.E. van Hinte et al. (eds.) Proc. Snellius II Symposium, Jakarta 1987, Netherlands J. Sea Research 24, 2/3, p. 345-356.
(SE Buru Wahlua and C Seram Tehoru metamorphic complexes similar pre-Triassic metamorphic history, and probably originated in same belt. Mylonites in N Tehoru indicate right-lateral, N300E directed strike-slip along transcurrent fault between metamorphics in S and non-metamorphic block in N, caused by anticlockwise rotation of Seram since Late Triassic. Kaibobo metamorphics T up to 740°C, caused by overriding ultramafic sheet in Late Miocene- E Pliocene. K/Ar ages of 4-5 Ma of micas from Wahlua and Tehoru complex explained by re-heating of pre-Triassic mica due to overthrusting by hot mantle slabs, now largely eroded. Average uplift of ~0.1 cm/yr during last 4-5 Ma in SE Buru and C Seram. Thrusting of metamorphics over non-metamorphics in 'median' Seram and of ultramafic sheet in SW Seram also related to Seram anticlockwise rotation)

Linthout, K., H. Helmers, J.R. Wijbrans & J.D.A.M. van Wees (1996)- 40Ar/39Ar constraints on obduction of the Seram ultramafic complex: consequences for the evolution of the southern Banda Sea. In: R. Hall & D.J. Blundell (eds.) Tectonic Evolution of SE Asia. Geol. Soc. London, Spec. Publ. 106, p. 455-464.
(On Kaibobo (SW Seram) obduction of hot oceanic lithosphere produced high-grade metamorphism and granite in overthrust continental crust. Ages from sole 5.65- 6.0 Ma and 5.4 Ma. Post-emplacement exhumation began < 8 Ma ago. Undoing 8 Ma of migration back-tracks Kaibobo to site where obduction ended: near SE corner of Banda Sea plate. Similarities between Kaibobo and N Timor ophiolites suggests E Miocene slow spreading in oceanic lithosphere S Banda Sea, S of current volcanic arc)

Liu, Z.Y.C. & R.A. Harris (2013)- Discovery of possible mega-thrust earthquake along the Seram Trough from records of 1629 tsunami in eastern Indonesian region. Natural Hazards, February 2013, p. 1-18.

(online at: http://link.springer.com/content/pdf/10.1007%2Fs11069-013-0597-y.pdf)
(Most likely source of mega-thrust earthquake that caused 15m high tsunami in 1629 at Banda Islands is Seram Trough, ESE of Seram Island. Mega-thrust earthquakes of magnitude needed to produce tsunami observed in Banda Islands have rupture lengths of >500 km)

(Brief summary of Pertamina fieldwork on Buru. Main sedimentary basin in S part of island, but gravity study suggests W and N parts of island may also have enough sediments for hydrocarbon accumulation)

O'Sullivan, T.D., D. Pegum, & J. Tarigan (1985)- Seram oil search, past discoveries and future oil potential. Proc. 14th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 3-20.
(Bula oilfield in E Seram discovered in 1897, produced >13 million barrels of oil have been produced, mainly form Pleistocene Fufa Fm. Seram is imbricate accretionary prism formed by subduction of Australian Plate. Shale diapirism and regional left-lateral wrenching important roles in structural development)

Panuju, J.S. Hadimulyono & J. Anwari (2015)- Hydrocarbons resource assessment of the eastern offshore area of Seram Island, Indonesia. Proc. 39th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA15-G-196, 15p.

Pairault, A.A., R. Hall & C.F. Elders (2003)- Tectonic evolution of the Seram Trough, Indonesia. Proc. 29th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, IPA03-G-013, p. 1-16.

Pairault, A.A., R. Hall & C.F. Elders (2003)- Structural styles and tectonic evolution of the Seram Trough, Indonesia. Marine Petroleum Geol. 20, 10, p. 1141-1160.
(Study of recent 2D seismic lines across Seram Trough in N part of Banda Arc, between Birds Head of New Guinea and Seram Island. Formerly interpreted as (1) subduction trench, (2) intra-continental thrust zone and foredeep, and (3) strike-slip fault zone. E Pliocene inversion of Misool-Onin anticlinorium produced angular unconformity, which truncates sediments as old as M Jurassic, later folded and now dippping S towards Seram Trough. Contraction in Trough occurred after E Pliocene and continues to present day. This work suggests Seram Trough is not subduction trench but foredeep within Australian continental margin, produced in response to loading by Seram fold-thrust belt. (This ignores dipping subducting slab as imaged by tomography, earthquake epicenters, also >100km wide accretionary prism, etc.; JTvG))

Patria, A. & R. Hall (2017)- The origin and significance of the Seram Trough, Indonesia. Proc. 41st Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA17-19-G, p. 1-19.
(Seram Trough commonly interpreted as accretionary wedge/ subduction zone beneath Seram, but is shallower than typical subduction zone and marks deformation front of fold-thrust belt resulting from young oblique convergence between Outer Banda arc and Birds Head. Fold-thrust belt zone narrower in W (with thrusting cesing thrusting ceases at E edge of Buru oceanic basin) and widens to SE. Thrusting at the trough started in Late Pleistocene)

Pownall, J.M. (2015)- UHT metamorphism on Seram, eastern Indonesia: reaction microstructures and P-T evolution of spinel-bearing garnet-sillimanite granulites from the Kobipoto Complex. J. Metamorphic Geol. 33, 9, p. 909-935.
(Seram Kobipoto Metamorphic Complex with Mio-Pliocene granulite facies migmatites and less common granulites. Migmatites associated with ultramafic rocks of lherzolitic composition, exhumed by lithospheric extension beneath low-angle detachment faults. Post-peak evolution of granulites may be related to published

U-Pb zircon and 40Ar/39Ar ages of ~16 Ma. Kobipoto Complex granulites demonstrate how UHT conditions may be achieved by extreme lithospheric extension, in this case driven by slab rollback of Banda Arc)

Pownall, J.M., R.A. Armstrong, I.S. Williams, M.F. Thirlwall, C.J. Manning & R. Hall (2018)- Miocene UHT granulites from Seram, eastern Indonesia: a geochronological-REE study of zircon, monazite and garnet. In: S. Ferrero et al. (eds.) Metamorphic geology: microscale to mountain belts, Geol. Soc. London, Spec. Publ. 478, p. 167-196.
(online at: http://searg.rhul.ac.uk/pubs/pownall_etal_2018%....)
(Ultra-high T (>900°C) garnet-sillimanite granulites of Seram formed by extensional exhumation of hot mantle rocks behind rolling-back Banda Arc. Miocene age confirmed by ~16 Ma zircons and monazites U-Pb ages. These geochronometers date retrograde overprints. Zircons shielded within garnet with 216-173 Ma ages (Late Triassic- E Jurassic. UHT conditions very short-lived and very rapid exhumation of granulite complex)

Pownall, J.M., M.A. Forster, R. Hall & I.M. Watkinson (2017)- Tectonometamorphic evolution of Seram and Ambon, eastern Indonesia: insights from 40Ar/39Ar geochronology. Gondwana Research 44, p. 35-53.
(Two main phases in Seram Neogene tectonic evolution: (1) 16 Ma episode of extreme extension that exhumed hot lherzolites from subcontinental lithospheric mantle and drove UHT metamorphism and melting of adjacent continental crust (kyanite-grade metamorphic event of Tehoru Fm across W and C Seram); and (2) 5.7, 4.5 and 3.4 Ma episodes of extensional detachment faulting and strike-slip faulting that further exhumed granulites and mantle rocks across Seram and Ambon. Events interpreted to be result of W Seram ripping off from SE Sulawesi, extended, and dragged E by Banda Slab subduction rollback)

Pownall, J.M. & R. Hall (2014)- Neogene extension on Seram: a new tectonic model for the northern Banda Arc. Proc. 38th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA14-G-305, 17p.
(Neogene tectonic evolution of Seram not dominated by thrusting and shortening due to collision of N Banda Arc with Australian passive continental margin, but peridotites represent subcontinental lithospheric mantle rapidly exhumed beneath low-angle detachment faults during extreme crustal extension. KobipotoMts of C Seram with peridotites intimately associated with granulite facies migmatite, recording ultrahigh P/T of 25-30 km depth. Granitoids emplacement across Seram and Ambon from 16 Ma (Kobipoto Mts) until 3.5 Ma (Ambon). Seram experienced extreme extension by detachment faulting best explained by E-ward rollback of Banda slab since 16 Ma)

Pownall, J.M., R. Hall & R.A. Armstrong (2017)- Hot lherzolite exhumation, UHT migmatite formation, and acid volcanism driven by Miocene rollback of the Banda Arc, eastern Indonesia. Gondwana Research 51, p. 92-117.
(N Banda Arc (Seram) exposes upper mantle lherzolites and lower crust granulite facies migmatites of 'Kobipoto Complex'. Granulites experienced ultrahigh-T (> 900˚C) at 16 Ma due to heat supplied by lherzolites exhumed during slab rollback in Banda Arc. Ages of detrital zircons from Kobipoto Complex 3.4 Ga- 216 Ma, suggesting W Papua/ W Australian Archean protolith and post-Late Triassic metamorphism. Zircons in granulites three later growth episodes: 215-173 Ma (= subduction beneath Birds Head and Sula Spur?), 25-20 Ma (collision between Sula Spur and N Sulawesi?), and ~16 Ma. 16 Ma zircon rims grew during M Miocene metamorphism and melting of Kobipoto complex rocks beneath Seram under HT-UHT conditions. Extension during continued slab rollback exhumed both lherzolites and adjacent granulites beneath extensional detachment faults in W Seram at 6.0-5.5 Ma, and on Ambon at 3.5 Ma. Ambonites and dacites sourced mainly from melts generated in Kobipoto Complex migmatites erupted on Ambon from 3.0-1.9 Ma.)

Pownall, J.M., R. Hall, R.A. Armstrong & M.A. Forster (2014)- Earthôs youngest known ultra high temperature granulites discovered on Seram, eastern Indonesia. Geology 42, 4, p. 279-282.
(late Early Miocene (16 Ma) ultrahigh-T (≥900 °C) granulite metamorphics in Kobipoto Mountains, Seram, youngest at Earth surface. Slab rollback-driven lithospheric extension caused metamorphic core complex-style exhumation of hot subcontinental lithospheric mantle)

Pownall, J.M., R. Hall & I.M. Watkinson (2013)- Extreme extension across Seram and Ambon, eastern Indonesia: evidence for Banda slab rollback. Solid Earth 4, 2, p. 277-314.

(online at: www.solid-earth.net/4/277/2013/se-4-277-2013.pdf)
(Seram island in N part of Banda Arc previously interpreted as fold-and-thrust belt formed during arc-continent collision, with ophiolites intruded by granites. New geological mapping and re-examination of field relations suggest recent N-S extension caused high-T exhumation of mantle peridotites and granites (Kobipoto Complex) beneath low-angle lithospheric detachment faults)

Price, P.L., T. OöSullivan & R. Alexander (1987)- The nature and occurrence of oil in Seram, Indonesia. Proc. 16th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 141-172.

('The Liassic of the Nief Gorge in East Seram'. In Nief Gorge very thin (60 cm) glauconitic limestone with Middle Liassic diverse brachiopods (Rhynchonella spp., Spririferina spp., Terebratula), cephalopods (Oxynoticeras, Phylloceras, Lytoceras, Dactylioceras, etc.), bivalves and gastropods (Pleurotomaria, etc.), overlying (Triassic?) massive oolitic limestone. Most species related to European Tethys faunas)

Wanner, J., H.C.G. Knipscheer & E. Schenk (1952)- Zur Kenntnis der Trias der Insel Seran (Indonesien). Eclogae Geol. Helvetiae 45, 1, p. 53-84.
(online at: http://retro.seals.ch/cntmng?type=pdf&rid=egh-001:1952:45::440&subp=hires)
('On the knowledge of the Triassic of Seram'. Good documentation of NE Seram Late Triassic (Carnian-Norian) 'flysch', limestones and macrofossils. Carnian dominated by clays, marls, quartz sandstones with plant debris; Norian more platy limestones, marly limestones and calcareous sandstones. Upper Norian with lenses of massive Lovcenipora- Halorella limestone. Lovcenipora coral limestones erroneously interpreted as Late Jurassic in age by Van der Sluis (1949) and Van Bemmelen (1949). Similar Upper Triassic limestones in C Seram, S Buru and Timor. Triassic macrofaunas dominated by Tethyan elements like Monotis salinaria, Halobia spp. and Juvavites. Triassic overlain by Jurassic- Cretaceous deep water marls and limestones. Rare loose fossil material suggests limited presence of E-M Jurassic. Upper Jurassic represented by marly calcareous shales with Aucella malayomaorica and Belemnopsis gerardi)

Weber, F. (1926)- Eindrapport omtrent het geologisch onderzoek en den vooruitzichten van Oost Ceram. BPM Report 9611, p. *(Unpublished)*
('Final report on the geological survey and the prospectivity of East Seram'. Unpublished BPM report. Sediment series of E Seram starts with Upper Triassic; no older sediments present. Carnian-Norian flysch is poor in fossils. On S coast of Seram Triassic sequence is locally complete and includes~100m thick late Norian limestone, the base of which is bitumen-impregnated and has asphaltic joint fillings. In E part of S Mountains 300-400m thick oolitic limestone. E Seram folded/uplifted above sea level in E Eocene: in narrow strip N of the S mountains is pink coarse lime-sandstone with Eocene Nummulites and Alveolina, and Cretaceous is missing. Main folding-thrusting in Seram is towards end of Miocene)

Welter, O.A. (1923)- Bemerkungen uber die von Deninger gesammelten Ammoniten und Nautilidenreste von Seran. Palaeontographica, Suppl. 4, III, 4, p. 245.
('Remarks on the ammonite and nautilid fossils collected by Deninger from Seram'. Appendix in Krumbeck (1923) Seram brachiopod/mollusc paper. Fragments of Upper Triassic ammonites (Choristoceras, Anatomites, Juvavites) and nautilids (Phoioceras) from C Seram resemble species known from Timor and of 'alpine' affinity)

Wichmann, C.E.A. (1898)- Der Wawani auf Amboina und seine angeblichen Ausbruche (parts 1-2). Tijdschrift Kon. Nederlands Aardrijkskundig Genootschap (2), 15, p. 1-20 and p. 200-218.
('The Wawani on Ambon and its reported eruptions, parts 1-2)')

Wichmann, C.E.A. (1899)- Der Wawani auf Amboina und seine angeblichen Ausbruche (part 3). Tijdschrift Kon. Nederlands Aardrijkskundig Genootschap (2), 16, p. 109-142.
('The Wawani on Ambon and its reported eruptions, part 3'. Wawani mountain on Ambon with diabase and porphyric igneous rock, but is not a volcano)

Wilckens, O. (1937)- Korallen und Kalkschwamme aus dem obertriadischen Pharetronenkalk von Seran (Molukken). Beitrage zur Palaontologie des Ostindischen Archipels 14, Neues Jahrbuch Mineral. Geol. Palaeont., Beilage Band B77, p. 171-211.
('Corals and calcareous sponges from the Upper Triassic Pharetronen-limestone of Seram'. Triassic corals and sponges of Seram and Timor have 'alpine' character. Includes new coral species Thecosmilia alfurica, Isastrea seranica, etc., and new calcareous sponge genera Deningeria, Seranella, Cryptocoelia. Flugel (2002, p. 420) suggested W Seram Late Triassic corals and sponges mostly endemic taxa or taxa known from Timor, but Martini et al. (2004) found no endemic fauna, only species of Tethyan affinity. Flugel also suggests close similarities with Timor Fatu Limestone)

Xi, Z., X. Hu, Y. Fang, X. Yin & H. Du (2016)- Tectonic evolution of North Seram Basin, Indonesia, and its control over hydrocarbon accumulation conditions. China Petroleum Exploration 21, 6, p. 1-8.
(online at: www.cped.cn/CN/item/downloadFile.jsp?filedisplay=20161230153808.pdf)
(N Seram Basin evolution interpreted as four stages: E Triassic initial rifting, M Triassic- M Jurassic rifting, Late Jurassic- M Miocene passive continental margin and Late Miocene-Quaternary thrusting of foreland foldbelt (Seram and Birds Head viewed here as part of same continental block; no subduction/collision))

Zillman, N.J. & R.J. Paten (1975)- Geology and petroleum prospects of Seram island, eastern Indonesia. Australian Petrol. Explor. Assoc. (APEA) J. 15, p. 73-80.
(Two main Pliocene- E Pleistocene basins in N and NE Seram (Bula and Wahai) with up to 1400/ 2800m of sediment. Oil seeps common in Bula but not in Bahai basin. Bula field 1897 discovery in Pleistocene clastics; producing horizons ~80-280m below SL. Folded Pre-Tertiary rocks regarded as basement by BPM and AAR. Middle or Late Miocene folding preceded Early Pliocene renewed subsidence. Early Pleistocene uplift created rel. subtle regional unconformity.

Zillman, N.J. & R.J. Paten (1975)- Petroleum prospects, Bula Basin, Seram, Indonesia. Proc. 4th Ann. Conv. Indon. Petroleum Assoc. (IPA), 2, p. 129-148.
(Plio-Pleistocene Bula Basin with Early Pleistocene unconformity. Bula field 1897 BPM discovery below surface oil seep in shallow Pleistocene sands, producing since 1913. Limited hydrocarbons and potential in Mesozoic Nief limestone)

VII. BANDA SEA, LESSER SUNDA ISLANDS

VII.1. Banda Sea, East Banda Arc (incl. Tanimbar, Kai, Aru)

Abimanyu, R., J. Bates, J. Boast et al. (1996)- Tanimbar Basin. In: Pertamina/BPPKA (ed.) Petroleum geology of Indonesian Basins IX, p. 1-32.

Achdan, A. & T. Turkandi (1982)- Geologic map of the Kai and Tayandu Islands, Maluku, Quadrangle 2810, 2910, scale 1:250,000. Geol. Res. Dev. Centre Indonesia, Bandung.
(Second edition of 1982 map. ?Pre-Cambrian metamorphic rocks on Kur and Fadol Islands (biotite schist and granitic gneiss). Oldest rocks on Kai M Eocene Yamtimur Fm marls with planktonic foraminifera and 700m thick M-U Eocene Elat Fm limestones with Lacazinella wichmanni, Discocyclina, Nummulites, Alveolina; unconformably overlain by Late Oligocene Tamingil Lst and Oligocene- M Miocene Meduar Lst)

Agustiyanto, D.A, M. Suparman, E. Partoyo & D. Sukarna (1994)- Geological map of the Moa, Damar and Bandanaira sheets, Maluku, Quadrangles 2607, 2707, 2708, scale 1:250.000. Geol. Res. Dev. Center, Bandung.
(Geology of outer arc islands E of Timor: Kisar, Leti, Moa. Also active Banda Sea volcanoes Damar, Serua, Nila. South Leti with Permian sandstones; most of island Permian? metamorphics and ultrabasics)

Agustiyanto, D.A, M. Suparman, E. Partoyo & D. Sukarna (1994)- Geological map of the Babar sheet, Southeast Maluku, scale 1:250.000. Geol. Res. Dev. Center, Bandung.
(Most of Babar island Mio-Pliocene melange with blocks of ?Permian metamorphics, Permo-Triassic limestone, Jurassic shales, ophiolite (equivalent of Bobonaro Complex of Timor). Also minor Jurassic shales with ammonites and belemnites) (equivalent of Wailuli Fm of Timor). Sermata Island with ?Permian metamorphic rocks only)

Bowin, C., G.M. Purdy, C. Johnston, G. Shor, L. Lawver, H.M.S. Hartono & P. Jezek (1980)- Arc-continent collision in Banda Sea region. American Assoc. Petrol. Geol. (AAPG) Bull. 64, p. 868-915.
(Elaborate, key paper on E Indonesia tectonic history. The Banda Outer Arc of Timor, etc., contains fragments of Australian crust that probably rifted off in Jurassic time, collided with Sulawesi and split off and collided with Australian continental margin in last 3 My. Water depths of 5km and low heatflow values (1.1. HFU average) suggest ages of Banda Sea basins >60 Ma)

Bowin, C. & C. Johnston (1981)- Arc-continent collision in Banda Sea region: reply. American Assoc. Petrol. Geol. (AAPG) Bull. 65, p. 867.
(Response to Crostella (1981). Reiterate they regard all Timor rocks N of Kolbano thrust belt as originally part of pre-collision Banda Arc outer arc ridge)

Burhanuddin, S. (1994)- Geologie des bassins de la Mer de Banda (Indonesie). Ph.D. Thesis, Universite de Bretagne Occidentale, Brest, p. 1-197. *(Unpublished)*
('Geology of the Banda Sea basins'. Grab samples from North Banda Basin seafloor suggest crust of NE Banda Basin is oceanic to transitional, and is a Late Miocene backarc basin dated as 7-10 Ma. Exact age of South Banda Basin remains unknown. Triassic platform carbonate and island arc volcanics sampled from the N part

of Banda Ridges. Volcanic arc remnants successively younger in southern direction. Banda Sea domain currently under compression)

Burhanuddin, S., J.A. Malod, Ulva R., F. Hinschberger & Sultan (1999)- A new morphology and discovery of sea mount in the basin between Ambon and Buru islands: result of Image IV Expedition. In: I. Busono & H. Alam (eds.) Developments in Indonesian tectonics and structural geology, Proc. 28th Ann. Conv. Indon. Assoc. Geol. (IAGI), Jakarta, 1, p. 43-49.
(New submarine volcano between Buru and Ambon in small 4000m deep E Buru basin. Seamount water depth range from -3600m- -200m. Dredge samples andesitic volcanics. Part of Pliocene- Quaternary Ambelau-Ambon volcanic arc of Honthaas et al. 1998)

Burhanuddin, S., L. Sarmili, J.P. Rehault, J.A. Malod, R.C. Maury, H. Bellon, Y. Anantasena & Syaefuddin (1994)- Cekungan Laut Banda Utara (Indonesia Timur): suatu sketsa baru punggungan Tampomas dan batuan dasar samuderanya. Proc. 23rd Ann. Conv. Indon. Assoc. Geol. (IAGI), Jakarta, 1, p. 509-519.
('The North Banda Sea Basin (E Indonesia): a new sketch of the Tampomas ridge and oceanic basement'. New bathymetric map confirms oceanic nature of North Banda Sea. Main morphological feature in N Banda Sea is NW-SE trending Tampomas Ridge, SW of Buru, interpreted as remnant strike-slip fault. Pillow lavas dredged from E flank indicate Late Miocene (9 ±3Ma) back-arc basin floor (cross-section looks like big rotated fault block with 2 sec of relief; JTvG))

Burollet, P.F. & C.L. Salle (1985)- Tectonic significance of the Banda Sea. Proc. 14th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 2, p. 477-490.
(Geological reconnaissances in Kai and Tanimbar Archipelagoes show E-W succession of: (1) folded Paleogene-Miocene of Australian borderland and accretionary wedges; (2) Neogene basins with overpressured shales and mud volcanoes; (3) melange olistolites or nappes overthrusting part of Neogene basins; (4) Pre-Tertiary basement terranes in W part. Banda Sea represents stretched internal sea)

Bursch, J.G. (1947)- Mikropalaontologische Untersuchungen des Tertiars von Gross Kei (Molukken). Schweizerische Palaontol. Abhandlungen, 65, 3, p. 1-69.
('Micropaleontological investigations of the Tertiary of Kai Besar'. Well-illustrated descriptions of limestones with Eocene (incl. Lacazina; should be Lacazinella; JTvG) and Early Miocene larger forams)

Callomon, J.H. & G. Rose (2000)- Middle Jurassic ammonites from the island of Babar in the southern Moluccan forearc, Indonesia. Revue Paleobiologie, Geneve, Spec. Vol. 8, p. 53-64.
(M Jurassic ammonites from outcrops on Babar. Fauna dominated by Satoceras satoi (=Macrocephalites group), a bioprovincially Austral sphaeroceratid genus, unknown in W Tethys, but characterizes Late Bajocian-Early Callovian, and known also from Sula and W Irian Jaya)

Charlton, T.R., M.E.M. de Smet, H. Samodra & S.J. Kaye (1991)- The stratigraphic and structural evolution of the Tanimbar islands, eastern Indonesia. J. Southeast Asian Earth Sci. 6, 3-4, p. 343-358.
(Stratigraphy of Tanimbar islands comparable to other Banda forearc islands like Timor, with Australian continental margin sequences added to forearc/collision complex by accretionary processes. Oldest rocks M-Late Triassic sandstones and E-M Jurassic grey shales, found only in ejecta of mud volcanoes. Oldest rocks in normal outcrop is Ungar Fm sandstone of probable Late Jurassic-E Cretaceous age. Major unconformity cut out Late Cretaceous-Paleogene. Miocene siliciclastic Tangustabun Fm and succeeding carbonate clastic Batimafudi Fm deformed in Pliocene, and unconformably overlain by E Pleistocene-Recent post-orogenic sediments. Structurally Tanimbar comparable to W Timor)

Charlton, T.R., M.E.M. de Smet, H. Samodra & S.J. Kaye (1991)- Stratigrafi dan perkembangan struktur di Kepulauan Tanimbar, Indonesia Timur. Bull. Geol. Res. Dev. Centre 16, p. 45-69.
(Indonesian version of above paper)

Charlton, T.R., S.J. Kaye, H. Samodra & Sardjono (1991)- Geology of the Kai Islands: implications for the evolution of the Aru Trough and Weber Basin, Banda Arc, Indonesia. Marine Petroleum Geol. 8, 1, p. 62-69.

(E Kai islands dominated by normal faults, downthrowing to Aru Trough, with no sign of earlier compressive forearc deformation. Aru Trough extensional feature, in direct bathymetric continuity with compressional Timor-Tanimbar Trough. Banda Arc thrust front steps W-ward as result of extension in Aru Trough. Thrust front runs N-S through Kai group, separating inactive accretionary complex to W from active extension in E. Weber Basin results from E-W extension, with pre-existing thrust faults probably reactivated in extension as low-angle normal faults. Both compressional and extensional deformation since Pliocene)

Charlton, T.R., S.J. Kaye, H. Samodra & Sardjono (1991)- Geologi kepulauan Kai dan implikasinya terhadap perkembangan Palung Aru dan Cekungan Weber, Indonesia Timur. J. Geologi Sumberdaya Mineral 3, 18, p. 2-11.
('Geology of the Kai islands...' Indonesian version of Charlton et al. 1991, above)

Cornee, J.J., J. Butterlin, P. Saint-Marc, J.P. Rehault, C. Honthaas et al. (1998)- An Early Miocene reefal platform in the Rama Ridge (Banda Sea, Indonesia). Geo-Marine Letters 18, p. 34-39.
(Early Miocene reefal carbonate with Lepidocyclina (N) dredged from Rama Ridge, indicating Banda Sea ridges were present in Early Miocene, with major tectonic subsidence between M Miocene and E Pliocene. (Age assignment may be questioned; could also be Late Oligocene or Middle-Late Miocene; JTvG))

Cornee, J.J., M. Villeneuve, M. Ferrandini, F. Hinschberger et al. (2002)- Oligocene reefal deposits in the Pisang Ridge and the origin of the Lucipara Block (Banda Sea, Eastern Indonesia). Geo-Mar Letters 22, p. 66-74.
(M-L Oligocene reefal deposits with Pararotalia mecatepecensis and pelagic E Pliocene muds dredged from Pisang Ridge in Banda Sea, confirming it is part of continental/ continental arc Lucipara Block (incl. Tukang Besi, Lucipara and Rama ridges). Lucipara Block drifted from N Irian Jaya in M Miocene and collided with Kolonodale Block in Late Miocene. A late Early Oligocene volcanic arc developed in Weber Trough area, then uplifted to shallow-water position at Early-Late Oligocene boundary in Pisang Ridge. Late Oligocene- E Miocene metamorphism subsequently developed, prior to deposition of E Miocene coral reefs in Rama Ridge. Locally, Late Miocene metamorphism identified in Lucipara Ridge, prior to latest Miocene-Pliocene drowning and splitting of Lucipara Block into several small blocks throughout Banda Sea region)

Cornee, J., M. Villeneuve, J.P. Rehault, J. Malod, J. Butterlin, P. Saint-Marc, G. Tronchetti et al. (1997)- Stratigraphic succession of the Australian margin between Kai and Aru islands (Arafura Sea, eastern Indonesia), interpreted from Banda Sea II cruise dredge samples. J. Asian Earth Sci. 15, 4-5, p. 423-434.
(Dredges in Aru Trough E of Kai Besar recovered fairly complete Australian margin section, 3000-4000m thick, from ?Carboniferous- Permian to Jurassic- Miocene. Displaced Eocene carbonate with Lacazinella)

Cox, L.R. (1924)- Some Late Kainozoic pelecypoda from the Aru Islands. Geol. Magazine 61, 2, p. 56-63.

'Active diapirs/ mud volcanoes in the SE Moluccas'. Tanimbar and Kei islands are active diapirs. On mud volcanoes on Tanimbar and Kai islands. About 30 young diapyrs identified on Tanimbar islands. With brief descriptions of geologic setting)

Hinschberger, F., J.A. Malod, J. Dyment, C. Honthaas, J.P. Rehault & S. Burhanuddin (2001)- Magnetic lineations constraints for the back-arc opening of the Late Neogene South Banda Basin (Eastern Indonesia). Tectonophysics 333, p. 47-59.
(New analysis of magnetic lineations E part of S Banda (Damar) Basin infers opening in Late Miocene- E Pliocene, 6.5- 3.5 Ma. Cessation of spreading probably arc-continent collision at ~3 Ma. Damar basin began as intra-arc basin, separating Banda arc in S from incipient Lucipara arc to N)

Hinschberger, F., J.A. Malod, J.P. Rehault, J. Dyment, C. Honthaas, M. Villeneuve & S. Burhanudin (2000)- Origine et evolution du bassin Nord-Banda (Indonesie): apport des donnees magnetiques. Comptes Rendus Academie Sciences, Paris, Earth Planetary Sci. 331, p. 507-514.
(N Banda Sea Basin opened in Late Miocene in back arc setting. Magnetic, bathymetric data and radiometric dates from dredges of its basement used to depict basin evolution. Sea floor spreading occurred from 12.5- 7.15 Ma directed by three large NW-SE transform faults, West Buru, Tampomas and Hamilton fracture zones)

Hinschberger, F., J.A. Malod, J.P. Rehault & S. Burhanuddin (2003)- Apport de la bathymetrie et de la geomorphologie a la geodynamique des mers de lŒst-Indonesien. Bull. Soc. Geologique France 174, 6, p. 545-560.
(online at: http://documents.irevues.inist.fr/bitstream/handle/2042/283/019-034.pdf?sequence=1)
(N and S Banda Seas and Weber Trough formed in Neogene by back-arc spreading and slab roll-back. Magnetic anomalies define ages of 12.5- 7.1 Ma for N Banda Basin and 6.5- 3.5 Ma for S Banda Basin. Weber Trough >7300m deep, remains enigmatic. N Banda Basin SE rifted margin morphology preserved along Sinta Ridges. Basin presently in compression and crust subducted W under E Sulawesi. N border N Banda Basin

reactivated into sinistral transcurrent motion in S Sula Fracture Zone. S Banda Sea two parts (Wetar, Damar), separated by NNW-SSE volcanic Gunung Api Ridge, interpreted as sinistral strike-slip zone. Dredging of Triassic limestones and metamorphic basement suggests Sinta and Rama Ridges are continental block fragments. Banda Ridges fringed to S by Nieuwerkerk- Emperor of China- Lucipara volcanic chains with andesites and basalts of 8- 3.5 Ma. New volcanic seamount SE of Buru and volcano on Pisang Ridge with sub-aerial volcanic morphology and subsidence evidenced by reefal limestones on flank, now at ~3000m depth. Basement depths ~1000m below age-depth curve for back-arc basins and ~2000m below curve for oceanic crust. Except for one M Eocene (46-Ma) N-MORB type basalt (from ophiolitic complex?), Basalts-andesites dredged from Banda Sea ridges of Neogene ages (Tukang Besi ~10 Ma, Nieuwerkerk- Emperor of China 8-7 Ma, Lucipara 7-3 Ma). Lucipara- Nieuwerkerk- Emperor of China and Wetar segment of Banda Arc were part of single volcanic arc at 8-7 Ma, with subduction of Indian Ocean continental crust below continental blocks of Australian origin, followed by back-arc rifting/ spreading. End of magmatic activity at 3 Ma result of collision of Timor with Wetar segment of Sunda arc)

Honthaas, C., J.P. Rehault, R.C. Maury, H. Bellon, C. Hemond, J.A. Malod, J.J. Cornee, M. Villeneuve et al. (1998)- A Neogene back-arc origin for the Banda Sea basins: geochemical and geochronological constraints from the Banda ridges (East Indonesia). Tectonophysics 298, p. 297-317.
(Except for one M Eocene (46-Ma) N-MORB type basalt (thought to belong to ophiolitic complex), volcanics dredged from Banda Sea ridges all Neogene age: ~10 Ma for Tukang Besi back-arc basalts, 8-7 Ma for Nieuwerkerk–Emperor of China calc-alkaline andesites and 7-3 Ma for Lucipara OIB-type transitional basalts and cordierite-bearing andesites. Isotope signatures suggest assimilation of continental crust. Lucipara- Nieuwerkerk- Emperor of China Ridges and Wetar segment of Banda Arc parts of single volcanic arc at 8-7 Ma, with subduction of Indian Ocean continental crust below continental blocks of Australian origin, followed by back-arc rifting/ spreading. End of magmatic activity on both volcanic segments at 3 Ma thought to result from collision of Timor with Wetar segment of Sunda arc.

Honthaas, C., M. Villeneuve, J.P. Rehault, H. Bellon, J.J. Cornee et al. (1997)- Kur island: geology of the Eastern flank of the Weber Trough (Eastern Indonesia). Comptes Rendus Academie Sciences, Paris 325, 11, p. 883-890.
(Data from Kur Island and nearby dredgings show unknown events on E margin of Weber basin: (1) E Oligocene magmatic arc; (2) E Miocene metamorphism event between 24-17 Ma; and (3) E Pliocene deformation, related to Australian plate- Banda arc collision. Weber basin was created in Pleistocene with uplift of E margin)

Huang, Y.S., T.Q. Lee, S.K. Hsu & T.N. Yang (2009)- Paleomagnetic field variation with strong negative inclination during the Brunhes chron at the Banda Sea, equatorial southwestern Pacific. Physics Earth Planetary Interiors 173, p. 162-170.
(Analysis of paleomagnetic variation of last 820 kyr in core from Banda Sea)

Hutchison, C.S. (1977)- Banda Sea volcanic arc: some comments on the Rb, Sr and cordierite contents. Warta Geologi (Newsl. Geol. Soc. Malaysia) 3, 2, p. 27-35.
(online at: https://gsmpubl.files.wordpress.com/2014/09/ngsm1977002.pdf)
(Unusually high Rb/Sr ratios in volcanic rocks and cordierite in rhyolite at Tanjong Illipoi (Wetar) indicate strong continental crustal influence in source of volcanic rocks. Romang also with higher Rb/Sr ratios than active volcanic arc. Wetar different from other islands of Banda Arc because of abundant light grey rhyolite and dacite. This extinct, eroded and uplifted portion of Banda volcanic arc N of Timor affected by subducted Australian continental Plate. Cordierite in rocks of Ambon also imply continental crustal basement in N part of Banda Arc)

Hutchison, C.S. & P.A. Jezek (1978)- Banda Arc of eastern Indonesia: petrography, mineralogy and chemistry of the volcanic rocks. In: P. Nutalya (ed.) Proc. 3rd Regional Conf. Geology and Mineral Resources of SE Asia (GEOSEA III), Bangkok, Asian Inst. Techn., p. 607-619.

(Four distinct volcanic rock series in Neogene Banda arc: High-K alkaline andesites (Gunung Api, Damar, etc.), calcalkaline andesites (Serua, Manuk), tholeitic basalts (Ambon, Banda Neira, Kelang), cordierite-bearing dacites and rhyolites (Ambon))

Lapouille, A., H. Haryono, M. La Rue, S. Pramumijoyo & M. Lardy (1985)- Age and origin of the seafloor of the Banda Sea (eastern Indonesia). Oceanologica Acta 8, 4, p. 379-389.
(Magnetic anomalies of Banda Sea oceanic crust tied to Cretaceous, suggesting plate is piece of trapped Indian Ocean floor crust. (More recent work suggests Miocene age of oceanic crust; JTvG))

Lee, C.S. & R. McCabe (1986)- The Banda-Celebes-Sulu Basin: a trapped piece of Cretaceous-Eocene oceanic crust? Nature 322, 6074, p. 51-54.
(Banda, Celebes and Sulu basins poorly understood marginal seas. Banda basin possibly trapped oceanic basin once continuous with Late Jurassic Argo abyssal plain. Celebes and Sulu basins also underlain by oceanic crust. Celebes and Sulu Seas may have been continuous with Banda basin. (NB: most of suggested Cretaceous ages proven wrong by subsequent ODP wells, dredge results, etc.; Hutchison 1992, etc.))

Leybourne, B.A. & N.B. Adams (1999)- Modeling mantle dynamics in the Banda Sea triple junction:exploring a possible link to El Nino Southern Oscillation. OCEANS 99 MTS/IEEE. Riding the Crest into the 21st Century 2, 2, p. 955-966.
(Evaluation of mantle depths from gravity and seismic studies indicates upwelling of mantle from ~30-40 km under continental shelf of Australia to 21 km in Banda Arc. From here mantle rises to 14 km in Weber Deep and reaches depth of 7 km in N Banda Sea. Seismic epicenter data delineate spatial boundaries of flow regimes and define magmatic migration routes. Epicenter magnitudes are visualized in 3 dimensions by color-coding. Animation portrays upwelling and divergence of mantle flow structures (geostreams) underlying tectonic trends of region and resulting counterflow in volcanic arcs based on 'surge tectonic' hypothesis)

Linthout, K., H. Helmers & J. Sopaheluwakan (1997)- Late Miocene obduction and microplate migration around the southern Banda Sea and the closure of the Indonesian Seaway. Tectonophysics 281, 1-2, p. 17-30.
(Ultramafites on Timor N coast, on smaller islands in S Outer Banda Arc and on SW Seram are fragments of M Miocene oceanic lithosphere, obducted in Late Miocene. Cool sole rock metamorphosed by overriding oceanic lithosphere. Kaibobo lherzolitic complex (SW Seram) obduction started ~9.5 Ma, emplacement completed at ~8 Ma and fast vertical movements continued until ~7 Ma. Obduction of lherzolite on N Timor also at 8 Ma and cooling to 300° C at 5.5 Ma. Oceanic lithosphere formed in E Miocene (~6 Ma prior to start of obduction). Obducted ultramafites formed close to passive margin by slow spreading in short-lived interarc Timor Plate (16-9.5 Ma). Model good agreement with 9.9-7.5 Ma history of shallowing and closure of Indonesian Seaway, as inferred from biogeographic patterns and thermal evolution of Miocene equatorial Pacific waters)

Martin, K. (1890)- Die Kei-Inseln und ihr Verhaltniss zur Australisch-Asiatischen Grenzlinie, zugleich ein Beitrag zur Geologie von Timor und Celebes. Tijdschrift Kon. Nederlands Aardrijkskundig Genootschap (2), 7, p. 241-280.
('The Kai islands and their relevance to the Australian-Asian boundary'. Study of rocks from Kai islands collected by Wertheim in 1889. Miocene larger foram limestone from Kai Besar up to 2000' elevation with large orbitoids. Also Eocene limestones with alveolinid (re-identified as Lacazinella by Verbeek 1908). No figures; not overly useful)

McCaffrey, R. (1989)- Seismological constraints and speculations on Banda Arc tectonics. In: J.E. van Hinte et al. (eds.) Proc. Snellius II Symposium, Jakarta 1987, Netherlands J. Sea Research 24, 2-3, p. 141-152.
(Australian continent- Banda Arc collision shortens overriding Indonesian plate in N-S direction and elongates it in E-W direction by combination strike-slip and thrust faulting. Two plates subduct beneath Banda Arc: (1) Australia-Indian Ocean plate N-ward beneath Java Trench-Timor Trough-Aru Trough, and (2) Birds Head SW-ward beneath Seram Trough. Slab of Indian Ocean plate forms W-ward plunging synform beneath Banda Basin. Birds Head lithosphere subducted under Seram Trough down to 300 km depth. At surface decoupling between Australian and Birds Head by left-lateral strike slip at Tarera-Aiduna fault zone and convergence in New Guinea foldbelt. Seismic quiescence 50-380 km beneath Timor and inactive volcanic arc, but S-wave propagation suggests continuous lithospheric slab)

McCaffrey, R. & G.A. Abers (1991)- Orogeny in arc-continent collision: the Banda arc and western New Guinea. Geology 19, p. 563-566.
(Shallow earthquakes show crustal deformation in Banda Arc and W New Guinea dominated by thrust and strike-slip faulting. Tarera- Aiduna left-lateral strike slip zone (~20mm/year) and New Guinea thrust belt accommodate WSW motion of Birds Head with respect to Australia. Left-lateral Sorong- Yapen fault zone accommodates main part of Australia -Pacific relative motion (~80mm/year). Possible E-ward extrusion of Banda Arc may be 40mm/yr. Seismic zone of Seram subduction zone beneath Seram at least 600km long)

Merton, H. (1910)- Forschungsreise in den sudostlichen Molukken (Aru- und Kei-Inseln) im Auftrage der Senckenbergischen Naturforschenden Gesellschaft. Abhandl. Senckenberg Naturforschenden Gesellschaft, Frankfurt, p. 1-208.

Michael-Leiba, M.O. (1984)- The Banda Sea earthquake of 24 November 1983: evidence for intermediate depth thrust faulting in the Benioff zone. Physics Earth Planetary Interiors 36, 2, p. 95-98.
(24 November 1983, major earthquake at 180 km depth beneath Banda Sea. Shear failure took place within NNW dipping Benioff zone by thrust faulting along S-dipping plane. Focal mechanism solution does not conform to usual pattern and could not caused by down-dip tension or compression within sinking slab)

Milsom, J. (1999)- The Banda Sea: continental collision at the eastern end of Tethys. In: G.H. Teh (ed.) Proc. 9th Reg. Congress Geology, Mineral and Energy Resources of SE Asia (GEOSEA ô98), Kuala Lumpur 1998, Bull. Geol. Soc. Malaysia 43, p. 41-47.
(online at: https://gsmpubl.files.wordpress.com/2014/09/bgsm1999005.pdf)
(Banda Sea is Late Neogene post-collisional collapse basin, similar to Tyrrhenean and Alboran Seas in Mediterranean (arcuate orogenic belts with outward-directed thrusts enclosing rapidly expanding extensional regimes). New oceanic basins produced by rollback have depths typical of much older crust. Timor and Seram may have been part of M Miocene Sulawesi orogen prior to Banda Sea extensional collapse (This and Milsom 2000, 2001 papers are first to propose Banda Sea creation by Late Neogene slab rollback extension, before similar models were proposed in Hinschberger et al. (2003, 2005) and Spakman and Hall (2010))

Milsom, J. (2005)- The Vrancea seismic zone and its analogue in the Banda Arc, Eastern Indonesia. Tectonophysics 410, p. 325-336.
(Comparison of Carpathian orogenic belt with Banda Arc. Intermediate depth earthquakes define subducted slab that dips N, S and W beneath Banda Sea, a configuration explained as consequence of rapid expansion of Banda Sea during roll-back subduction)

Milsom, J., M.G. Audley-Charles, A.J. Barber & D.J. Carter (1983)- Geological-geophysical paradoxes of the Eastern Indonesian collision zone. In: T.W.C. Hilde & S. Uyeda (eds.) Geodynamics of the Western Pacific-Indonesian region, American Geophys. Union and Geol. Soc. America (GSA) Geodyn. Ser. 11, p. 401-412.

Milsom, J., S. Kaye & Sardjono (1996)- Extension, collision and curvature in the eastern Banda arc. In: R. Hall & D. Blundell (eds.) Tectonic Evolution of Southeast Asia, Geol. Soc., London, Spec. Publ. 106, p. 85-94.
(Discussion of compressional deformation front between Kai Besar- Kai Kecil islands. Eocene- Pleistocene sediments on Kai Besar never deeply buried or imbricated but experienced large-scale extensional faulting. Associated gravity high requires upfaulting of accretionary complex, attenuated Australian continental crust on which it rests and underlying mantle at W side of Aru Trough. Deformation front in Aru Trough is SE of Kai Islands but entirely to W further N. Instead of continuing NNE to offset near New Guinea coast, collision trace passes through strait between Kai Besar and other islands, and mimics smooth curve of gravity contours, rather than discontinuities of bathymetric troughs. Continuity in deep and shallow structures is evidence for existence of outer arc as single geological unit prior to present phase of arc-continent collision)

Milsom, J., Sardjono & A. Susilo (2001)- Short-wavelength, high-amplitude gravity anomalies around the Banda Sea, and the collapse of the Sulawesi Orogen. Tectonophysics 333, p. 61-74.

(Ophiolitic rocks around Banda Sea commonly associated with strong gravity anomalies and steep gradients, but relationships not always straightforward. Bouguer gravity levels and gradients over E Sulawesi ophiolite generally low. In Banda Arc, most positive ophiolite anomalies on steep regional gradient but in W Seram distinct spatial separation. On Buru >10 mGal/km gradient suggests dense rocks near surface, despite absence of ophiolites in outcrop. Gravity variations and ophiolite distribution around Banda Sea compatible with extension in Sulawesi following Oligo-Miocene collision with Australian-derived microcontinent. Association of ultramafic rocks and local strong regional gravity gradient is largely coincidental)

Nasution, A., I. Takashima, H. Takahashi, K. Matsuda, H. Akasako, H. Muraoka, D. Kusnadi, F. Nanlohi & M. Futagoishi (2000)- The geology and geochemistry of Mataloko-Nage-Bobo geothermal areas, Central Flores, Indonesia. In: Proc. World Geothermal Congress, Kyushu- Tohoku 2000, p. 2165-2170.

Prasetyo, H. (1999)- Marine geology and tectonic development of the Banda Ridges system, eastern Indonesia; implication for Banda marginal basin formation. In: Proc. 35th Session Comm. Co-ord. Joint Prospecting Mineral Resources in Asian Offshore Areas (CCOP), Subic Bay 1998, 2, Techn. Repts., p. 11-38.
(Banda Sea neither young spreading basin nor trapped piece of oceanic crust, although N (Sula) and S (Banda) basins appear to be trapped Pre-Tertiary oceanic crust. Banda Ridges in central part composed of continental borderland formed in Irian Jaya and emplaced in present position by Late Miocene. Basement rock dredged from Banda Ridge can be correlated with similar lithologies on Irian Jaya, Misool, Buru and PNG. Banda Ridge Terrane overlain by Upper Miocene- younger sediments that consist of pelagic limestones and Miocene volcanic rocks in the Lucipara Islands)

Purdy, G.M. & R.S. Detrick (1978)- A seismic refraction experiment in the Central Banda Sea. J. Geophysical Research 83, p. 2247-2257.
(Seismic refraction experiment in C Banda Sea suggests oceanic crustal structure, with velocities typical of oceanic layers 2, 3A, and 3B and mantle. Layer 3B unusually thick (2.5-4.6 km); greater than normal depths to Moho of 9-10 km below sea floor. These and earlier results from S Banda basin indicate that entire Banda Sea is underlain by oceanic type crust)

Rehault, J.P., J.A. Malod, M. Larue, S. Burhanuddin & L. Sarmili (1991)- A new sketch of the central North Banda Sea, eastern Indonesia. J. Southeast Asian Earth Sci. 6, p. 329-334.
(New bathymetric map of oceanic North Banda Basin. NW-SE structural pattern appears to be result of orientation of large NW-SE strike-slip faults and present direction of NE-SW convergence. Faulting and underthrusting of N Banda Sea crust beneath E Sulawesi along active Tolo accretionary prism)

Rehault, J.P., R. Maury, H. Bellon, L. Sarmili, S. Burhanuddin, J.L. Joron, J. Cotten & J.A. Malod (1994)- La mer de Banda Nord (Indonesie): un bassin arriere-arc du Miocene superieur. Comptes Rendus Academie Sciences, Paris 318, p. 969-976.
(Pillow-lavas dredged from basement of N Banda Sea are transitional basalts and trachyandesites with negative Nb-Ta anomalies similar to lavas from back-arc basins. K-Ar ages 9 and 6.9 Ma. Oceanic basement now subducting beneath E Sulawesi not trapped piece of Indian Ocean, but Late Miocene back-arc basin floor. (one of first papers after Hamilton (1979) to suggest Late Miocene back arc basin interpretation)

Verbeek, R.D.M. (1908)- Residentie Amboina. In: Molukkenverslag, Jaarboek Mijnwezen Nederlandsch Oost-Indie 37 (1908), Wetenschappelijk Gedeelte, p. 428-655.
(Early descriptions of islands of Banda arc, from E of Timor to Seram-Buru. Includes descriptions and cross-sections of Kai Besar and illustrations of Eocene Discocyclina- Asterocyclina from Kai. Oldest beds on Kai Besar weakly folded Eocene marly limestones, dipping 10° W. Overlain by horizontal limestone terraces, oldest with Lepidocyclina (Miocene), younger ones post-Miocene)

Villeneuve, M., J.J. Cornee, R. Martini, L. Zaninetti, J.P. Rehault, S. Burhanudin & J. Malod (1992)- Upper Triassic shallow-water limestones in the Sinta Ridge (Banda Sea, Indonesia). Geo-Marine Letters 14, p. 29-35.
(online at: https://archive-ouverte.unige.ch/unige:26438)
(10 dredge samples from N slope Sinta Ridge (separates N and S Banda basins). Some are shallow marine limestones with Upper Norian- Rhaetian? benthic foraminifera, (incl. Aulatortus, Triasina oberhauseri, Duostominidae). Similarities with E Sulawesi, Buru and Seram consistent with independent Upper Triassic block. Origin of Banda Sea microcontinents questionable)

Villeneuve, M., J.P. Rehault, J.J. Cornee, J.A. Malod, J. Clermonte, J.M. Auzende, L. Sarmili, S. Burhanuddin, G. Glacon, G. Tronchetti, L. Zaninetti & R. Martini (1993)- Plio-Quaternary evolution of the North Banda Sea and East Sulawesi margin. In: M.T. Zen (ed.) 10th anniversary of the French-Indonesian cooperation in oceanography; ocean research, technology and maritime industry, Jakarta 1993, Adiwarna Citra, Bandung, p. 109-118.
(online at: https://archive-ouverte.unige.ch/unige:26392)
(Cruise of vessel Baruna Jaya III provided new seismic data and dredge samples from W part of Sinta Ridge (incl. Triassic limestones). Late Miocene age of opening of North Banda Sea (6-9 Ma basalts). Continental Sinta Ridge went down from surface to 3000m during creation of N Banda Sea oceanic crust. General compressive regime in whole N Banda Sea)

Von Der Borch, C.C. (1979)- Continent-island arc collision in the Banda Arc. Tectonophysics 54, p. 169-193.
(Timor-Tanimbar-Ceram troughs and adjacent outer Banda Arc very similar to arcs subducting oceanic lithosphere and sediments, despite fact that outer Banda Arc is underlain by continental crust(??). Alignment with oceanic Indonesian Arc, gravity anomalies, and persistence of morphological and structural entities around arc favour subduction in Timor-Tanimbar-Ceram Troughs rather than gravity sliding towards troughs. Outer Banda Arc is accretionary prism of subduction zone which was formerly in ocean-crust setting but since

Pliocene has been interacting with continental lithosphere. This model for Banda Arc differs from other structural interpretations of Timor island, which is emergent outer arc)

Wandel, G. (1936)- Beitrage zur Kenntnis der Jurassischen Molluskenfauna von Misol, Ost Celebes, Buton, Seran und Jamdena. In: J. Wanner (ed.) Beitrage zur Palaeontologie des Ostindischen Archipels 13, Neues Jahrbuch Mineral. Geol. Palaontologie, Beilage Band 75B, p. 447-526.
('Contributions to the knowledge of Jurassic molluscs from Misool, East Sulawesi, Buton, Seram and Yamdena'. Description of Mollusca, mainly collected by F. Weber. Misool faunas include upper Liassic Harpoceraten beds, lower Dogger Hammoceraten beds, Oxfordian Aucella malayomaorica marls (also in E Sulawesi), etc.)

Wanner, J. & E. Jaworski (1931)- Liasammoniten von Jamdena und Celebes. Neues Jahrbuch Mineral. Geol. Palaontologie, Beilage Band 66, B, p. 199-210.
('Liassic ammonites from Yamdena and Sulawesi'. Sulawesi ammonites from poorly known central part of East arm, collected by BPM geologist Weber, are first records of Early Jurassic ammonites from E Sulawesi (Arnioceras cf. seilaeve from dark grey sandy limestone as float in upper Balingara River, 20km SE of river mouth). Yamdena ammonites from Tasik Selwasa and Botenjahu mud volcano deposits include Echioceras wichmanni, Asteroceras sparsicostatum n.sp. and Arnioceras cf. arnouldi. Fauna and lithology very similar to Krumbeck (1922)'s 'grey cephalopod nodule marl' of Roti and Timor)

(Magnetic anomalies may indicate volcanic material associated with topographic features in Aru and Weber Troughs. Discontinuity along W extension of Tarera-Aiduna Fault between Seram subduction zone and Aru Trough/ Kuenen Bank (larger variations of gravity to S and change in magnetic trends) although both gravity and magnetic anomalies exhibit NE-SW trend obliquely across SE section of Seram Trough. Seram Trench accretionary complex over dynamically-depressed crust of subducting plate. Weber Basin crust excessively depressed and thinned. Positive gravity anomalies suggest outer part of Timor-Tanimbar accretionary complex either above rising or shallower subducting plate, or contains substantial denser material. Major strike-slip feature may be present NE of Tanimbar, cutting accretionary complex obliquely)

(History of large 1990 Batu Hijau copper-gold porphyry discovery on SW Sumbawa by Newmont in 1990. Typical island arc porphyry deposit, hosted within tonalite intrusive complex in diorite and andesitic metavolcanics wallrock)

Fichtner, A., M. De Wit & M. van Bergen (2010)- Subduction of continental lithosphere in the Banda Sea region: combining evidence from full waveform tomography and isotope ratios. Earth Planetary Sci. Letters 297, p. 405-412
(Subduction of old continental lithosphere to >100 km under Banda arc suggested by tomographic images and isotope signatures in arc volcanics. Late Jurassic ocean lithosphere N of N Australian craton was capable of entraining large volumes of continental lithosphere. Timor tomographic images indicate island not directly above N margin of N Australian craton. Possible explanation involves delamination within continental crust, separating upper from lower crustal units, consistent with massive accretionary complex on Timor island, with evidence from Pb isotopes for lower-crust involvement in arc volcanism)

Fiorentini, M.L. & S.L. Garwin (2010)- Evidence of a mantle contribution in the genesis of magmatic rocks from the Neogene Batu Hijau district in the Sunda Arc, South Western Sumbawa, Indonesia. Contrib. Mineralogy Petrology 159, p. 819-837.
(Sumbawa island is E Miocene- Holocene volcanic arc built on oceanic crust. Low-K calc-alkaline magmatic suite of Sunda arc in Batu Hijau district with juvenile signature and minimal involvement of sediment component in arc petrogenesis. Arc-transverse fault system facilitated rise of mantle-derived melts above kink or tear in subducting Indian Ocean Plate under Sunda arc. De-hydrogenation of tonalite plutons may have been crucial to genesis of Cu-Au porphyry mineralization and development of Pliocene Batu Hijau deposit)

Franchino, A., E. Bellini & A. Brizio (1988)- Geological notes on the age of the limestones of the Island of Lombok. Indonesia. Memorie Scienze Geol., Padova, 40, p. 335-368.
(Lombok mainly composed of Tertiary volcanics, in S part associated with limestones and marls. At Sekotong Barang on SW coast isolated hills of Late Oligocene limestone (Te1-4; with Spiroclypeus, Eulepidina, etc.). Central southern hills limestones with Late Oligocene- E Miocene (Te4-Te5; Miogypsinoides) and M Miocene ages (Tf1; Lepidocyclina, Miogypsina) (limestone ages on Lombok partly older than Wonosari Limestone of S Java and Nusa Dua/ S Bali?; JTvG))

Garwin, S.L. (2000)- The setting, geometry and timing of intrusion-related hydrothermal systems in the vicinity of the Batu Hijau porphyry copper-gold deposit, Sumbawa, Indonesia. Ph.D. Thesis, University of Western Australia, Nedlands, p. 1-320. *(Unpublished)*
(~1500m thick E-M Miocene low-K calc-alkaline andesitic volcanoclastics of Sunda-Banda arc, with thin limestone interbeds, and cut by several phases of Mio-Pliocene intrusions. Sumbawa segment of arc overlies oceanic crust. Felsic magmatism and related hydrothermal systems between ~7.1- 3.7 Ma probably related to collision with microcontinent or leading edge of Australian Shelf and Banda Arc near Timor. Subduction of buoyant Roo Rise oceanic plateau, S of Sumbawa, inferred to have caused kink or tear in downgoing slab, which enhanced delivery of mantle-derived melts to overlying arc)

Garwin, S. (2002)- The geologic setting of intrusion-related hydrothermal systems near the Batu Hijau porphyry copper-gold deposit, Sumbawa, Indonesia. In: R.J. Goldfarb & R.L. Nielsen (eds.) Global Exploration in the 21st Century, Colorado, Soc. Economic Geol. (SEG), Spec. Publ. 9, p. 333-366.

(Study of forearc structures of E Sunda Arc. Seismic profiles show high along-strike variability of subducting oceanic plate, accretionary wedge, outer arc high, forearc basins, etc.. Images of large-scale duplex formation of oceanic crust and mud diapyrs. Wrench fault system in E Lombok forearc basin decouples subduction regime of Sunda Arc from continent-island arc collision regime of W Banda Arc)

Mangga, S.A., S. Atmawinata, B. Hermanto, B. Setyogroho & T.C. Amin (1994)- Geologic map of Lombok, Nusatenggara, sheet 1807, scale 1:250,000. Geol. Res. Dev. Centre (GRDC), Bandung.
(Lombok Island oldest rocks along S coast, composed of latest Oligocene- E Miocene Pengulung Fm volcanic breccias and lavas, overlain by Miocene Ekas Fm limestone and with Miocene dacite/basaltic intrusives (= 'Old Andesites'; continuation of Southern Mountains of Java - S Bali). N part of island mainly covered by Late Pliocene- Recent volcanics from Rinjani volcano complex)

Maryono, A. (2015)- Overview of the tectonic setting and geology of porphyry copper-gold deposits along the Eastern Sunda magmatic arc, Indonesia. In: World-class ore deposits: discovery to recovery, SEG 2015 Int. Conf., Hobart, 1p. *(Abstract only)*

(online at: www.segweb.org/SEG/_Events/Conference_Archives/2015/Conference_Proceedings/files/pdf/Oral-Presentations/Abstracts/Maryono.pdf)
(E Sunda arc major porphyry metallogenic belt (Tumpangpitu/ Tujuh Bukit Au-Ag-Cu deposit in E Java, Batu Hijau and Elang on Sumbawa). Porphyry mineralization confined to E segment (E Java to Sumbawa), where Roo Rise subducting beneath island arc. Subeconomic porphyry prospects at Selogiri, Ciemas, Cihurip with low sulfidation epithermal deposits (Pongkor, Cikotok, Cibaliung, Cikondang, Arinem) along W segment of Sunda arc, developed on thick continental crust on S Sundaland margin,d associated with 'normal' Indian oceanic crust subduction. Porphyry deposits typically with large lithocaps (>20 km2), with high sulfidation epithermal gold-silver veins within lithocaps at Elang, Selodong, Brambang and Tumpangpitu)

Maryono, A. & R. Harrison (2013)- Porphyry copper-gold mineralization styles along the Eastern Sunda magmatic arc, Indonesia. In: Proc. Symp. East Asia: Geology, exploration technologies and mines, Bali 2013, Australian Inst. Geoscient., Bull. 57, p. 58-59. *(Extended Abstract)*
(E Sunda magmatic arc with three world class porphyry Cu-Au deposits: Batu Hijau, Elang, Tujuh Bukit. All mineral deposits tied to magmatic arc intrusions of Late Miocene- Pliocene age: 3.7 Ma at Batu Hijau, 2.7 Ma at Elang, 7.5 Ma at Selodong, 2.5 Ma at Pongkor and 3.0 Ma at Arinem)

Maryono, A., R.L. Harrison, D.R. Cooke, I. Rompo & T.G. Hoschke (2018)- Tectonics and geology of porphyry Cu-Au deposits along the eastern Sunda magmatic arc, Indonesia. Economic Geology 113, 1, p. 7-38.
(E Sunda arc hosts three premier porphyry Cu-Au deposits between E Java and Sumbawa: Batu Hijau, Elang, and Tumpangpitu. Built on island-arc crust where Roo Rise is being subducted. Along W Java segment of arc major epithermal deposits associated with poorly endowed porphyry prospects, on thick continental crust of S margin of Sundaland, associated with subduction of thin Indian oceanic crust. Porphyry Cu-Au deposits associated with small, nested, dioritic-tonalitic intrusive complexes, with mineralization during three main events. Large (>20 km2) lithocaps with high-sulfidation epithermal systems. Porphyry deposits formed between 2-2.5 Ma, suggesting important change in metallogeny of arc at this time)

Maryono, A., R. Harrison, I. Rompo, E. Priowasono & M. Norris (2016)- Successful techniques in exploring the lithocap environment of the Sunda magmatic arc, Indonesia. In: Proc. 8th Ann. Conv. Masyarakat Geologi Ekonomi Indonesia (MGEI), Bandung, p. 7-13.
(On exploration techniques of large Cu-Au porphyry deposits under barren or mineralized lithocaps. Five major discoveries in last 15 years in E Java and Sumbawa)

(Same as Maryono et al. 2014)

Maryono, A., L.D. Setijadji, J. Arif, R. Harrison & E. Soeriaatmadja (2014)- Gold, silver and copper metallogeny of the eastern Sunda magmatic arc, Indonesia. Majalah Geologi Indonesia (IAGI) 29, 2, p. 85-99.
(online at: www.bgl.esdm.go.id/publication/index.php/dir/article_detail/847)
(Same as Maryono et al. 2012) (Recent discovery of large porphyry gold-silver-copper deposit at Tujuh Bukit Project in Banyuwangy Regency of E Java. E astSunda Magmatic Arc built on thin island arc crust, bounded by margin of Sundaland to W and by Australian continental crust to E. Five different ages of Cenozoic magmatic belts. Overwhelming number of gold, silver, and copper deposits associated with Late Miocene- Pliocene

intrusions. E Sunda magmatic arc dominated by gold, silver, and copper, in porphyry and epithermal deposits. Mineralization styles similar to those in typical island arc settings, e.g. the Philippines)

Masturyono (1994)- Seismicity of the Bali region from a local seismic network; constraints on Bali back arc thrusting. Masters Thesis, Rensselaer Polytechnic Institute, Troy, NY, p. 1-92. *(Unpublished)*
(Locations of 513 microearthquakes near Bali island. Deepest events at 200 km depth, associated with N-dipping Wadati-Benioff zone of subducting Indian ocean lithosphere. Two prominent belts of shallow micro earthquakes (1) S belt along boundary of Sunda- Indian ocean plates and (2) opposite-dipping zone along island arc, showing back-arc thrusting N of Bali, dipping 15 -20° S. Back arc thrusting extends to 30km depth below S coast of Bali island)

Maula, S. & B.K. Levet (1996)- Porphyry copper-gold signatures and the discovery of the Batu Hijau deposit, Sumbawa, Indonesia. In: Proc. Conf. Porphyry-related copper and gold deposits of the Asia Pacific Region, Cairns 1996, Australian Mineral Foundation, Glenside, p. 8.1-8.13.

McBride, J.H. (1987)- Arc-continent collision in the Banda Arc: new gravity observations integrated with geological and geophysical data. In: E. Brennan (ed.) Proc. Pacific Rim Congress 1987, Gold Coast, Australasian Inst. of Mining and Metallurgy (AusIMM), Parkville, p. 887-890.
(New marine gravity data and gravity models of transect across Timor- Savu Sea. Main issue is major negative anomaly over Savu Sea)

McBride, J.H. & D.E. Karig (1987)- Crustal structure of the outer Banda Arc; new free-air gravity evidence. Tectonophysics 140, p. 265-273.
(Gravity analysis of Timor- Sumba region. Mass deficit below Savu Sea may be subducted lighter continental crust, downward flexing of upper crustal plate in forearc area or anomalous low-density upper mantle. Gravity high over N Sumba Ridge in Savu Sea may be E-M Tertiary volcanic arc between present arc and Timor. Crust under N Savu Basin appears nearly oceanic, but thickens beneath modern arc)

McCaffrey, R. (1988)- Active tectonics of the eastern Sunda and Banda arcs. J. Geophysical Research 93, p. 15163-15182.
(E Sunda arc and S Banda arc and forearc respond to collision by shortening in direction of convergence, elongating normal to convergence, and thrusting over back arc basin. Shallow thrust and strike-slip earthquakes beneath Banda Basin demonstrate deformation in back arc accommodating some of N-ward motion of Australia. N-S shortening of upper plate near Timor ~20% of predicted Australia- SE Asia convergence. Strike-slip faulting in Banda Basin results in E-ward motion of Banda arc, with thrusting at Aru Trough. Weber forearc basin on subducting lithosphere, without intervening asthenosphere, so subsides in response to sinking of subducting lithosphere. Birds Head subducts beneath Seram, is decoupled from Australian plate in W New Guinea and probably moves W or SW with respect to Australia)

McCaffrey, R. (1989)- Seismological constraints and speculations on Banda Arc tectonics. In: J.E. van Hinte et al. (eds.) Proc. Snellius II Symposium, Geology and geophysics of the Banda Arc and adjacent areas, Jakarta 1987, Netherlands J. Sea Research 24, 2/3, p. 141-152.
(Shallow earthquakes show collision of Australian continent- Banda Arc shortens overriding Indonesian plate in N-S and elongates it in E-W direction by strike-slip and thrust faulting. Two plates subduct beneath Banda Arc: Australia-Indian Ocean plate N-ward and Birds Head SW-ward. Bird's Head subducted lithosphere beneath Seram Trough now reaches 300 km depth. At surface decoupling between Australia and Bird's Head probably by left-lateral strike slip at Tarera-Aiduna fault zone and convergence in New Guinea fold-and-thrust belt. Seismic quiescence at 50-380 km beneath Timor may result from removal of part of Australian continental crust prior to subduction of lower lithosphere; crust stacked up to form Timor Island)

McCaffrey, R., P. Molnar, W. Roecker & Y.S. Joyodiwiryo (1985)- Microearthquake seismicity and fault plane solutions related to arc-continent collision in the eastern Sunda arc. J. Geophysical Research 90, B6, p. 4511-4528.

(Microearthquakes used to model subducting Australian continental plate under Timor. Suggest leading edge of Australian continental lithosphere now at 150 km depth (at 45° slab angle that means subducted slab length = ~300km; at ~75km/My of convergence Australian margin continental crust arrived at Timor Trench at ~4 Ma). Fault plane solutions of several events show nearly vertical nodal planes trending parallel to strike of seismic zone, with down-to-NW displacement. These suggest subducted lithosphere presently detaching in 50-100 km depth range beneath E Savu Sea)

(Three submarine ridges off NE Flores waters: Baruna Komba (S of Komba/Batutara active volcano), Abang and Ibu. Magnetic data suggest Baruna Komba Ridge not volcanic, but possibly volcanic detritus. Abang and Ibu Komba ridges related to submarine magmatism)

Scotney, P.M. (2002)- The geology and genesis of massive sulphide, barite-gold deposits on Wetar Island, Indonesia. Ph.D. Thesis, University of Southampton, p. 1-220. *(Unpublished)*
(Pliocene volcanic hosted massive sulphide mounds ('black smoker deposits') at Wetar Island, with flanking Au-Ag-Hg-barite ore bodies. Island composed of Oligocene-Recent volcanics and minor oceanic sediments with mineralisation centers at Kali Kuning and Lerokis, ~3 km inland at 400-500m elevation. Orebodies adjacent to rhyodacite domes. 40Ar/39Ar age of biotite of syeno-granite intrusion 4.7 ± 0.2 Ma, from overlying dacitic flow 2.4 ± 0.3 Ma. Massive sulphides mainly pyrite with some chalcopyrite. Mining removed Au-Ag-bearing barite sands at Lerokis and Kali Kuning. Ore bodies covered by post-mineralisation Globigerina bearing limestone, submarine debris flows and pyroclastics. K-Ar illite age of altered footwall volcanics gives mineralisation age of 4.7 ± 0.16 Ma; 40Ar/ 39Ar age of same sample 4.5 ± 0.2 Ma)

Scotney, P.M., S. Roberts, R.J. Herrington, A.J. Boyce & R. Burgess (2005)- The development of volcanic hosted massive sulfide and barite-gold orebodies on Wetar Island, Indonesia. Mineralium Deposita 40, 1, p. 76-99.
(Wetar Island, Banda Arc, composed of Neogene volcanic rocks and minor oceanic sediments. Wetar volcanic edifice formed at ~12 Ma by extensive rifting and associated volcanism within oceanic crust. Youngest dated volcanic rock dacite of ~2. 4 Ma. 'Kuroko-type' volcanogenic precious metal-rich massive sulfide (mainly pyrite) overlain by barite deposits, which produced ~17 tonnes gold. Ages of hydrothermal alteration around ore bodies ~4.7-4.9 Ma. Sr isotopes of unaltered volcanic rocks suggest contributions from subducted continental material. Mineral deposits formed on flanks of volcano at water depth of ~2 km. Ore bodies covered by post-mineralization cherts, gypsum, Globigerina limestone, subaqueous debris flows and pyroclastics)

Self, S., M.R. Rampino, M.S. Newton & J.A. Wolff (1984)- Volcanological study of the great Tambora eruption of 1815. Geology 12, 11, p. 659-663.
(Tambora 1815 eruption one of largest explosive volcanic events of past 10,000 yr, with ~175 km3 of nepheline-normative trachyandesitic pyroclastic material was erupted in 24 hours. Plinian and co-ignimbrite ash fall >1 cm thick covered >500,000 km2 of Java Sea and surrounding islands)

Seran, H. & C. Farmer (2012)- Scratching at the surface: hidden mineralization at Wetar? In: N.I. Basuki (ed.) Proc. Banda and Eastern Sunda arcs, Indonesian Soc. Econ. Geol. (MGEI) Ann. Conv. 2012, Malang, p. 217-232. *(also in Majalah Geologi Indonesia (2013),28, 1, p. 51-63)*
(online at: www.bgl.esdm.go.id/publication/index.php/dir/article_download/720)
(Ongoing exploration for deeper metal prospects on Wetar Island. High sulfidation epithermal alteration may suggest presence of deeper porphyry style deposits that are related to known massive sulfides and extensive unexplored anomalies on island)

Setyandhaka, D. & J. Arif (2006)- Characteristics of the root of Cu-Au porphyry system: results of study from Batu Hijau Cu-Au porphyry deposit. Proc. 35th Ann. Conv. Indon. Assoc. Geol. (IAGI), Pekanbaru, 11p.

Setyandhaka, D., J. Proffett, S. Kepli & J. Arif (2008)- Skarn mineralization in Batu Hijau Cu-Au porpyry system. Proc. 37th Ann. Conv. Indon. Assoc. Geol. (IAGI), Bandung, 1, p. 664-671.
(Sumbawa Batu Hijau deposit classic Cu-Au porphyry system. Several intervals of calc-silicate rock and skarn interbedded with volcanics. Potential to find significant skarn-type mineralizations)

(2010)- Spatio-temporal characteristics of the geomagnetic field over the Lombok Island, the Lesser Sunda Islands region: New geological, tectonic, and seismo-electromagnetic insights along the Sunda-Banda Arcs transition. GoeForschungsZentrum, Potsdam, Scient. Techn. Report STR10/07, p. 1-115.
(online at: http://ebooks.gfz-potsdam.de/pubman/item/escidoc:10278:3/component/escidoc:10279/1007.pdf)

Zubaidah, T., M. Korte, M. Mandea, Y. Quesnel & M. Hamoudi (2014)- New insights into regional tectonics of the Sunda-Banda Arcs region from integrated magnetic and gravity modelling. J. Asian Earth Sci. 80, p. 172-184.
(Lombok Island lies between zones characterized by large intensity magnetic anomalies. Geomagnetic ground surveys and modelling suggest two active Quaternary normal faults and a magmatic arc related to subduction region. Magnetic anomalies and gravity models suggest extension of Flores Thrust zone (reaching NW off

Lombok Island). Flores Thrust zone may be considered as mature subduction in back arc region, showing tendency of progressive subduction during last decades)

Zubaidah, T., M. Korte, M. Mandea, Y. Quesnel & B. Kanata (2010)- Geomagnetic field anomalies over the Lombok Island region: an attempt to understand the local tectonic changes. Int. J. Earth Sciences (Geol. Rundschau) 99, 5, p. 1123-1132.

('Contribution to the geological study of Sumba island and relevance to the geodynamics of the east Indonesian archipelago')

Abdullah, C.I. (2010)- Evolusi magmatisme Pulau Sumba. Proc. 39th Ann. Conv. Indon. Assoc. Geol. (IAGI), Lombok, PIT-IAGI-2010-049, 3p.
('Magmatic evolution of Sumba Island'. Short paper describing three periods of calk-alkaline island arc magmatism in Cretaceous- Paleogene of Sumba: (1) U Cretaceous (Santonian- Campanian; 85.4- 78.6 Ma), (2) Maastrichtian- Thanetian (71.7- 56.6 Ma), (3) M Eocene- Oligocene (Lutetian- Rupelian; 42.3- 31.4 Ma)

Abdullah, C.I., J.P. Rampnoux, H. Bellon, R.C. Maury & R. Soeria-Atmadja (2000)- The evolution of Sumba Island (Indonesia) revisited in the light of new data on the geochronology and geochemistry of the magmatic rocks. J. Asian Earth Sci. 18, 5, p. 533-546.
(online at: http://directory.umm.ac.id/Data%20Elmu/jurnal/J-a/Journal%20of%20Asian%20Earth%20Science/Vol18.Issue5.2000/383.pdf)
(Sumba continental crustal fragment, with 3 Cretaceous-Paleogene arc volcanic episodes: Late Cretaceous (86-77 Ma), Maastrichtian- Thanetian (71-56 Ma) and Lutetian- Rupelian (42-31 Ma). W-ward shift of volcanism through time. No Neogene volcanism (considered reworked!?). Very similar to SW Sulawesi. Sumba was part of 'Andean' magmatic arc near SW Sulawesi magmatic belt and SE Kalimantan coast at margin of Asian Plate)

Abdullah, C.I., J.P. Rampnoux & R. Soeria-Atmadja (1996)- Data baru geochronologi, analysis kimia dan tinjauan geodinamik Pulau Sumba. In: Sampurno et al. (eds.) Pros. Seminar Nasional Geoteknologi III, LIPI, Bandung, p. 324-346.
('New data on geochronology, chemical analysis and review of geodynamics of Sumba Island'.Similar to above?. Sumba Block started to separate from Sundaland margin by oceanic rifting in Sumba Strait in Oligo-Miocene?)

Abdullah, C.I., E. Suparka & V. Isnaniawardhani (2008)- Sedimentary phases of Sumba Island (Indonesia). Proc. 37th Conv. Indon. Assoc. Geol. (IAGI), Bandung, 1, p. 66-79.
(Stratigraphy of Sumba continental block slightly to unmetamorphosed Cretaceous sediments, unconformably overlain by less deformed Tertiary-Quaternary deposits. Four sedimentary phases: (1) Late Cretaceous-Paleocene marine turbidites with Santonian-Campanian (86-77 Ma) and Maastrichtian- Thanetian (71-56 Ma) magmatic episodes; (2) Paleogene neritic sedimentation with Lutetian-Rupelian magmatic episode (42-31 Ma); (3) Neogene rapid sedimentation in deep sea environment; (4) Quaternary uplift of terraces. Sumba never subjected to intense deformation, implying never been involved in collision between Indian- Australian and Asiatic plates, except during minor compressive episode in Paleogene)

Audley-Charles, M.G. (1975)- The Sumba fracture: a major discontinuity between Eastern and Western Indonesia. Tectonophysics 26, p. 213-228.
(Sunda-Banda Arc not a continuous subduction system. Major tectonic discontinuity separates E Indonesia (Sumba, Banda Arcs, E Sulawesi) from W Indonesia (W Sulawesi and islands west of Sumba). Sumba fracture initially a Late Jurassic wrench fault that became Cretaceous and Cainozoic transform. Sumba detached from N Australia; Timor, etc., represent deformed Australian continental margin. Overthrust Asian elements also present. No subduction has taken place between Outer Banda Arc islands and Australia since Early Permian)

Audley-Charles, M.G. (1985)- The Sumba enigma: is Sumba a diapiric fore-arc nappe in process of formation? Tectonophysics 119, 1-4, p. 435-449.
(online at: http://searg.rhul.ac.uk/pubs/audley-charles_1985_Sumba%20enigma.pdf)

(Sumba Cretaceous-Miocene stratigraphy similar to Timor allochthonous Palelo-Cablac series and both with Cretaceous forearc deposits on thin continental crust. Postulated Sumba nappe not yet thrust onto Australian margin and may be diapyric dome)

(Sumba no subduction tectonics of Sunda Arc to W, nor collision tectonics of Banda Arc system. Sumba is continental fragment from Australia or from Sundaland (Flores Basin), that became trapped behind E Java Trench. Data not convincing, but appears to favor Australian origin)

Chamalaun, F. H. & W. Sunata (1982)- The paleomagnetism of the Western Banda Arc System-Sumba. In: Paleomagnetic Research in Southeast and East Asia, Proceedings of a CCOP Workshop, Kuala Lumpur 1982, p. 162-194.

Djoehanah, S. & S. Hadiwisastra (1984)- Korelasi umur nannoplangton dan foraminifera Paleogen di daerah Wanokaka, Sumba Barat. J. RISET Geologi Pertambangan (LIPI) 5, 1, p. 1-8.
(online at: http://pustaka.geotek.lipi.go.id/wp-content/uploads/2016/02/Riset-Vol.5-No.1-2.pdf)
(Samples from S coast of W Sumba, S of Waikabukak, with common Late Eocene (zone NP19) nannoplankton, incl. Discoaster barbadiensis, D. saipanensis, etc. From same horizon planktonic foraminifera of zone P16 (Hadiwisastra 1980) and zone Tb larger foraminifera (Caudri 1934))

Djumhana, N. & D. Rumlan (1992)- Tectonic concept of the Sumba continental fragment, Eastern Indonesia. Proc. 21st Ann. Conv. Indon. Assoc. Geol. (IAGI), Yogyakarta, 2, p. 585-598.
(Sumba island fragment of continental crust. Structure rel. simple. Seismic data suggest continuity with N part of Timor, from which it separated in M-L Miocene (11-10 Ma) and rotated 60° CW))

Effendi, A.C. & T. Apandi (1994)- Geology of the Waikabubak and Waingapu sheets, Nusatenggara. Geol. Res. Dev. Centre (GRDC), Bandung.
(1:250,000 geologic map of Sumba Island, originally completed in 1981. Oldest rocks recognized in outcrops is >1000m thick series of Upper Cretaceous deep marine flysch/greywacke with Globotruncana, associated with lavas and volcanic breccias and tuffs (Masu Fm). Intruded by Paleocene granodiorites (61.5 Ma) and andesitic volcanics, overlain by Eocene greywackes, Eocene and Lower Oligocene limestones and E Miocene andesitic volcanics (Jawila Fm.) Uplifted coral reefs suggest rapid recent uplift along N coastal areas (not in S))

Ely, K.S. & M. Sandiford (2010)- Seismic response to slab rupture and variation in lithospheric structure beneath the Savu Sea, Indonesia. Tectonophysics 483, 1-2, p. 112-124.
(Banda Arc earthquake focal mechanisms suggest subducting slab under W Savu Sea in down-dip compression at 70-300 km, while down-dip tension typifies intermediate depth Sunda slab to W and Banda slab to E. Compression reflects subduction of transitional crust of Scott Plateau. Enhanced magma flux indicated by narrower volcano spacing in overlying arc. E of Savu Sea, near complete absence of intermediate depth seismicity attributed to slab window where Australian continental crust has collided with arc. Differences in seismic moment release around this slab window indicate asymmetric rupture, propagating to E faster than W. Volcano spacing from Bali-Sumbawa average 68 km, in E Banda Arc average of 72 km)

Fleury, J.M. (2005)- De la subduction oceanique a la subduction continentale deformations associees et heritage structural: l'exemple du bloc Sumba-Savu, terminaison orientale du fosse de la Sonde. Thesis Universite Pierre & Marie Curie, Paris, p. 1-278. *(Unpublished)*

(East of 120ºE abrupt change in style of subduction deformation of upper plate. Fieldwork on Sumba demonstrated volcanic activity from Upper Cretaceous until Oligocene, followed by well-developed carbonate sedimentation. Miocene paleogeography shows E-W oriented platform- basin configuration. Currently Sumba is extensional regime. Savu Basin is marine extension of Sumba structure. Internal part is little deformed and acts as rigid buttress and transfers convergence to backarc. Arrival of Australian margin at subduction zone forms, at end of Mio-Pliocene orogeny in Timor, a rigid block composed of Sumba island in W, Timor in E and the little deformed Savu Basin in middle. W limit of this block unknown)

Reed, D.L. (1985)- Structure and stratigraphy of the eastern Sunda forearc, Indonesia. Geologic consequences of arc-continent collision. Ph.D. Thesis, Scripps Inst. Oceanography, La Jolla, University of California, p. 1-235. *(Unpublished)*
(Study of marine seismic profiles and piston cores in E Sunda fore-arc, with geologic fieldwork on Late Miocene- E Pliocene accretionary complex on Savu island. Savu with imbricated, well-indurated U Triassic-Jurassic quartzose turbidites/ deep water limestones (mainly ENE trending and WNW-dipping?) and more intensely deformed, sheared, poorly consolidated Cretaceous- Tertiary pelagic sediments (with scaly clays). Sumba Ridge best described as continental landmass (crustal thickness 24km), trapped in forearc during Miocene initiation of E Sunda arc-trench system, but rel. undeformed in Neogene. Between Sumba and Savu outflow of Pacific Ocean deep from Savu Basin water caused significant (up to 1000m?) submarine erosion on crests of ridges, with material re-deposited along Savu Thrust and Sumba Basin (mainly as muddy contourites/ drifts). Triassic limestones on Savu with Monotis salinaria, Halobia and radiolaria. U Jurassic with blocks of pillow basalts. Deformed strata on Savu never deeply buried. Blocks ('boudins'?) and scaly matrix formed by common deformation process. Opposite sense of imbrication along N and S coasts? Rel. undeformed U Miocene-Pliocene marls overlie U Miocene scaly clay of deformed section of Savu; uplifted >2km. N-directed backthrust N of Savu separates forearc basin from accretionary wedge. Refraction line across Savu Basin indicates oceanic crust)

Reed, D.L., A.W. Meyer, E.A. Silver & H. Prasetyo (1987)- Contourite sedimentation in an intraoceanic forearc system: Eastern Sunda Arc, Indonesia. Marine Geology 76, p. 223-241.
(Sedimentation in E Sunda forearc strongly influenced by vigorous deep- and bottom-water circulation. Sumba Ridge and Savu-Timor Ridge together form barrier to outflow of Pacific Ocean Deep Water from Savu Sea to E Indian Ocean. Outflow bottom currents eroded gap in sill at 1150m between Sumba and Savu. SW of gap, exposure of consolidated M Miocene- Pliocene foraminiferal chalks and oozes along Sumba Ridge suggests up to 1 km of overburden removed by currents. Eroded sediments re-deposited as muddy contourites in >1 km sediment drift in adjacent Sumba Basin. Drift forms elongated mound of reworked calcareous ooze and is bounded by moat-like channels)

Reed, D.L., E.A. Silver, H. Prasetyo & A.W. Meyer (1986)- Deformation and sedimentation along a developing terrane suture: Eastern Sunda forearc, Indonesia. Geology 14, p. 1000-1003.
(Discussion of Savu thrust, a S-dipping reverse fault thrusting Savu-Timor terrane Neogene accretionary wedge towards Sumba Ridge terrane, which is part of Banda forearc)

Rigg, J.W.D. & R. Hall (2011)- Structural and stratigraphic evolution of the Savu Basin, Indonesia. In: R. Hall et al. (eds.) The SE Asian gateway: history and tectonics of Australia-Asia collision. Geol. Soc. London, Spec. Publ. 355, p. 225-240.
(Savu Basin located in Sunda-Banda forearc at change from oceanic subduction to continent-arc collision. Interpreted to be underlain by continental crust, added to Sundaland margin in mid-Cretaceous. Before M Miocene Sumba and Savu Basin close to sea level and subsided rapidly in late M Miocene in response to extension induced by subduction rollback at Banda Trench)

Rigg, J.W.D. & R. Hall (2012)- Neogene development of the Savu Forearc Basin, Indonesia. Marine Petroleum Geol. 32, p. 76-94.

(Savu Basin records M Miocene initiation of subduction of Banda oceanic embayment, subsequent arc volcanism and Pliocene- Recent collision of Australian continent and Banda forearc. Four Neogene units: Unit 1 underlain by continental crust and Cretaceous-Paleogene arc rocks, capped by Oligocene- Lower Miocene shallow water carbonates. Subduction rollback-induced extension in M Miocene caused subsidence to depths of several km. Units 2-4 include M Miocene-Pliocene arc-derived volcaniclastic turbidites and deep water carbonates. Savu Basin little deformed, except near Savu and Roti Thrusts. Sumba Ridge elevated as Australian margin continental crust underthrust forearc to form broad flexure, tilting older units. Savu- Roti Ridge is pre-collision Banda forearc accretionary complex and Australian margin sedimentary cover and has risen >2 km since 2 Ma)

Roep, T.B. & A.R. Fortuin (1996)- A submarine slide scar and channel filled with slide blocks and megarippled *Globigerina* sands of possible contourite origin from the Pliocene of Sumba, Indonesia. Sedimentary Geology 103, p. 145-160.
(Early Pliocene deep-water sequences (~1-2 km deep) near Kambatatana, Sumba island, include slide scar which evolved into channel, >120m wide, 20m deep. Origin of the megarippled planktonic foraminiferal sand-units uncertain, but they may have been by contour currents)

Van der Werff, W. (1995)- Cenozoic evolution of the Savu Basin, Indonesia: forearc basin response to arc-continent collision. Marine Petroleum Geol. 12, 3, p. 247-262.
(Savu Basin initial E Miocene subsidence of outer forearc basin and development of M-Late Miocene volcanic 'proto' arc in S of basin resulted from Late Oligocene-E Miocene E-ward propagation of Java-Timor Trench. N of accretionary prism, forearc basement flexed down and reshaped into trenchward- dipping backstop that facilitates backthrusting of accretionary prism. Southern forearc basement probably acted as barrier against compression. Thickness of continental basement critical in response of forearc- continent collision. Savu Basin responded to underthrusting of continental crust by reactivation of basement ridges. This resulted in differentiation of forearc basin into extinct and uplifted Miocene S Savu Basin and Pliocene-Recent active N Savu Basin. Late Miocene-Recent uplift of large segments of outer forearc and subsidence of N Savu Basin)

Van der Werff, W. (1995)- Structure and morphotectonics of the accretionary prism along the Eastern Sunda-Western Banda Arc. J. Southeast Asian Earth Sci. 11, p. 309-322.
(Forearc region near Sumba- Savu variation in structure related to incipient collision with Australia. Arc-trench system changes from ridged S of Bali- Lombok- Sumbawa to sloped S of Sumba. E of Sumba, accretionary wedge backthrust over forearc basin, incorporating forearc sediments and basement. Accretionary wedge probably little of sediment subducted. Decrease in width of prism from Bali to Sumbawa corresponds to E-ward younging trend of arc-trench system from Late Oligocene to E Miocene. S of Sumba width of prism increases considerably, due to accretion of thick continental margin carbonates which deform by thrust-bounded folds. Buoyancy of partially subducted marginal Scott plateau increases basal shear stresses, adding to growth of large accretionary wedge. Further E, subduction of thick continental crust results in even higher basal shear stresses distributed through accretionary wedge, causing backthrusts and internal deformation, leading to shortening and thickening of wedge)

Van der Werff, W. (1996)- Forearc development and early orogenesis along the eastern Sunda/ western Banda arc (Indonesia). Ph.D. Thesis Vrije Universiteit, Amsterdam, pp. 1-311. *(Unpublished)*
(Collection of 7 previously published 1992-1996 papers, mainly on Snellius II seismic and land program in E Sunda- W Banda fore arc areas)

Van der Werff, W., D. Kusnida, H. Prasetyo & T.C.E. van Weering (1994)- Origin of the Sumba forearc basement. Marine Petroleum Geol. 11, 3, p. 363-374.
(Basement structures in E Sunda/ W Banda forearc suggests continuity between Sumba and N Timor. Structures trend E-W in W, gradually change into NE-SW trends in E. Major NE-SW trending discontinuity W of Sumba between 117° 30' and 118° 30' E marks transition between intraoceanic volcanic arc system in W and volcanic arc-continent collision zone in E. Extent of Sumba basement suggests either common (Late Jurassic) rift/drift history for Sumba and N Timor or (E Miocene) magmatic welding of two continental fragments of different origin, resulting in structural continuity between two microplates)

Van der Werff, W., H. Prasetyo & T.C.E. van Weering (1991)- The accretionary wedge South of Sumba Timor: an accreted terrane in the process of slivering? Proc. Int. Seminar on Geodynamics of fore-arc sliver plate, Indon. Assoc. Geophys. (HAGI), p. 55-60.

Van der Werff, W., H. Prasetyo, D. Kusnida, & T.C.E. van Weering (1994)- Seismic stratigraphy and Cenozoic evolution of the Lombok forearc basin. Marine Geology 117, p. 119-134.
(Lombok Basin probably underlain by thinned rifted continental crust. Five Cenozoic seismostratigraphic sequences (1) Paleogene synrift deposits, predating initiation of convergent margin; (2) and (3) two phases of evolution of accretionary prism, between Late Oligocene and M Miocene; (4) and (5) slope front fill deposits reflecting volcanic activity and tectonic uplift of magmatic arc from M Miocene onwards. By Late Miocene, increased convergence between subducting Indian and overlying Asian plates resulted in stronger mechanical

coupling, expressed in southern forearc basin by folding of oldest basin fill. Present activity governed by Late Pliocene collision of accretionary prism with Scott marginal and Roo Rise oceanic plateaus, resulting in uplift of outer-arc ridge and southern part of forearc basement)

Van Gorsel, J.T. (2012)- No Jurassic rocks on Sumba? Berita Sedimentologi 25, p. 35-37.
(Identification of an ammonite fragment from SW Sumba as M Jurassic Hammatoceras by Roggeveen (1929) is highly questionable, and Cretaceous age is more likely. Oldest proven rock age on Sumba is thus Cretaceous)

Van Weering, T.C.E., D. Kusnida, S. Tjokrosapoetro, S. Lubis, P. Kridoharto & S. Munadi (1989)- The seismic structure of the Lombok and Savu forearc basins, Indonesia. In: J.E. van Hinte et al. (eds.) Proc. Snellius II Symposium, Jakarta 1987, Netherlands J. Sea Research 24, 2-3, p. 251-262.
(Four seismic sequences in Lombok and Savu forearc basins, separated by unconformities (Late Oligocene, mid-Miocene and Pliocene S of Java). Upper Miocene- Pleistocene forearc fill turbidite-dominated. Faulting strongest in E Lombok Basin; growth faults, shale diapirs and mud volcanoes reflect intensity of deformation caused by merge of Sunda and Banda Arc collision systems. Tilted and uplifted basement ridges W of Sumba separate turbidite filled sub-basins from forearc basin. Sumba was in present position before onset of Sunda - Banda Arcs subduction system and initial Lombok and Savu forearc basins were connected)

(online at: www.geology.byu.edu/wp-content/uploads/2013/03/2004-Vorkink-Michael-W.pdf)
(Savu island is uplifted part of Banda fore-arc accretionary wedge, W of Timor. Consists of N and S verging thrust sheets of Late Triassic- M Jurassic Australian continental margin sediments, rimmed by discontinuous melange belt. Pillow basalts in Jurassic Wai Luli Fm. Detachment probably in Triassic Lower Babulu/ upper Aitutu Fm, at depth of ~2600m. Foraminifera in syn-orogenic deposits of Savu suggest water depths of 1-1.5 km at 1.8 Ma)

Vorkink, M.W. & R.A. Harris (2004)- Tectonic development of the incipient Banda Arc-continent collision: geologic and kinematic evolution of Savu Island, Indonesia. Abstracts with Programs Geol. Soc. America 2004 Annual Mtg., Denver, 36, 5, p. 319. *(Abstract only)*
(Savu both N and S-verging thrust sheets of Late Triassic- M Jurassic distal NW Australian continental margin units, rimmed by discontinuous melange of forearc basement fragments and synorogenic units. Pillow basalt in Jurassic Wai Luli Fm. N-verging folds move back of accretionary wedge over S Savu forearc basin. S-verging thrust sheets are bulk of island and well-exposed in S Savu. Detachment for thrust sheets in Triassic Lower Babulu or upper Aitutu Fms at ~2600m depth. Maximum age for initiation of collision 4.0 Ma. Foraminifera in syn-orogenic units indicate outer arc was at 1.0-1.5 km below sea level at 1.8 Ma, a surface uplift rate of ~1 mm/yr. At this rate, it takes 3.2-5.0 Ma to uplift these from pre-collisional depth of 3.5-4.0 km)

Wensink, H. (1991)- The paleoposition of the island of Sumba, derived from paleomagnetic data. In: E.P. Utomo, H. Santoso & J. Sopaheluwakan (eds.) Proc. Silver Jubilee Symposium on the Dynamics of subduction and its products, Yogyakarta 1991, Indonesian Inst. Sciences (LIPI), p. 238-244.

Wensink, H. (1994)- Paleomagnetism of rocks from Sumba: tectonic implications since the Late Cretaceous. J. Southeast Asian Earth Sci. 9, p. 51-65.
(online at: https://dspace.library.uu.nl/handle/1874/19116)

(Overview of Sumba geology. In Late Cretaceous Sumba was at 8° (not sure if N or S, but both demonstrate Sumba was not part of Australia at that time). In this paper concluded to various CCW rotations between Late Cretaceous and Miocene, but re-interpreted to more reasonable CW rotations in Wensink 1997)

Wensink, H. (1997)- Palaeomagnetic data of Late Cretaceous rocks from Sumba, Indonesia; the rotation of the Sumba continental fragment and its relation with eastern Sundaland. Geologie en Mijnbouw 76, p. 57-71.
(Paleomagnetic studies on Sumba continental fragment. Tanadaro granodiorite (65 Ma) paleolatitude 8.3° S. E Sundaland with Borneo, W and S Sulawesi, and Sumba formed one continental unit in Late Mesozoic, most likely attached to SE Asian mainland. Borneo and W and S Sulawesi large CCW rotations since Jurassic (45° in Cretaceous, 45° in Paleogene). Sumba microcontinent detached from E Sundaland soon after Late Cretaceous. Paleomagnetic data show Sumba underwent CW rotations of up to 96° (CW 53° between 82-65 Ma; 38° between 65-37 Ma; 9° between Late Eocene-Late Miocene and ~4° CCW since Late Miocene- E Pliocene). E Sundaland and Sumba close to equator since Jurassic)

Wensink, H. & M.J. van Bergen (1995)- The tectonic emplacement of Sumba in the Sunda-Banda Arc: paleomagnetic and geochemical evidence from the Early Miocene Jawila volcanics. Tectonophysics 250, p. 15-30.
(online at: http://dspace.library.uu.nl/handle/1874/19118)
(Paleomag of E Miocene Jawila arc volcanics suggests very similar position to present-day Sumba. Original position of Sumba in Late K- Paleocene probably 18° N; drift and rotation completed before Mid Miocene? Early Miocene arc volcanics on Sumba suggest island arc and imply older arc S of modern arc (= same as Java 'Old Andesites'?; JTvG), or was within E Sunda arc between Sumbawa and E Flores and drifted S. (NB: Fortuin et al. (1997) and Abdullah et al. (2000) suggest Jawila Volcanics Late Eocene- E Oligocene age)

Audley-Charles, M.G. (1967)- Greywackes with a primary matrix from the Viqueque formation, Upper Miocene-Pliocene, Timor. J. Sedimentary Petrology 37, 1, p. 5-11.
(Silt-clay matrix of post-orogenic Mio-Pliocene Viqueque Fm is primary detrital deposit, not result of diagenesis of sand grains. Basal conglomerates contain metamorphic and volcanic rocks as well as Triassic limestone)

Audley-Charles, M.G. (1967)- Petrology of a Lower Miocene polymict intracalcirudite from Timor. Sedimentary Geology 1, p. 247-257.
(Base E Miocene Cablac Limestone is unconformity: polymict conglomerate, incl. variety of carbonate rocks, volcanics, Cretaceous deep water carbonates and cherts, Triassic sandstones, etc.)

Audley-Charles, M.G. (1968)- The geology of Portuguese Timor. Mem. Geol. Soc. London 4, p. 1-76.
(Originally Ph.D. Thesis University of London, 1965. Classic E Timor study. Oldest dated rocks Lower Permian age. Metamorphic rocks interpreted as probably pre-Permian. Most formations autochthonous. Four formations completely allochthonous: Lolotoi Complex, Aileu Fm, Maubisse Fm and Bobonaro Scaly Clay. Bobonaro Scaly Clay emplaced as submarine gravity slide, and unlike other allochthonous formations does not rest on thrust-plane. 'Autochthonous' Aitutu Fm up to 1000m thick with rich, mainly Carnian-Norian faunas)

Audley-Charles, M.G. (1972)- Cretaceous deep-sea manganese nodules on Timor: implications for tectonics and olistostrome development. Nature Physical Sci. 240, 102, p. 107-139.
(Cretaceous manganese nodules of W Timor, first described by Molengraaff, resemble deep-sea nodules of modern oceans. Occur with micronodules in red clay similar to deep-sea red clays. Chemistry and physical characters suggest deposition on ocean floor, now at ~480m above sea level ('Maubisse seamounts' of Tethys Ocean, incorporated in Bobonaro melange))

Audley-Charles, M.G. (1973)- Paleoenvironmental significance of chert in the Franciscan Formation of western California: discussion concerning the significance of chert in Timor. Geol. Soc. America (GSA) Bull. 84, p. 363-368.
(Discussion of Chipping (1971) paper, who argued that cherts in Timor (following Grunau 1965) are 'important constituent' of melange and reflect subduction of oceanic crust beneath continental crust. However, chert is relatively insignificant in Timor melange and no evidence of subduction of oceanic crust below continental crust in Timor region since Early Permian. Chert in Timor reflects lack of supply of coarse terrigenous detritus and formed above sedimentary sequence on continental crust close to outer margin of continental slope)

Audley-Charles, M.G. (1981)- Geometrical problems and implications of large-scale overthrusting in the Banda arc- Australian margin collision zone. In: K. McClay & N.J. Price (eds.) Thrust and nappe tectonics, Geol. Soc. London, Spec. Publ. 9, p. 407-416.
(Geometrical problems in structural history interpretion of Australia-Banda Arc collision zone (mainly Timor area): (1) apparent absence of subduction trench and accretionary arc-trench gap in Banda Arc; (2) location of surface trace of Benioff zone before collision; (3) history of Benioff zone after Pliocene oceanic trench was destroyed; (4) relationship of developing fold- thrust belt to pre-collision geometry of Australia-New Guinea continental margin; (5) apparent absence of continental slope and rise in N Australia collision zone; (6) relationship of crystalline basement of Outer Banda Arc to cover rocks and (7) tectonic significance of apparent continuity of stratigraphically and structurally different Sunda and Banda Arcs. Australia- Banda arc collision associated deformation, represented by folding-imbrication of Australian continental rise sediments of Outer

Banda Arc with emplacement of overthrust exotic sheets, was accomplished in 2 My. Geometrical considerations suggest Benioff zone and most of ~200 km wide arc-trench gap were overridden by Australian lithospheric plate during continued plate convergence of last 3 My. Banda Arc fold-thrust belt developed in proximal continental rise deposits at foot of Australian continental slope)

Audley-Charles, M.G. (1986)- Timor-Tanimbar Trough: the foreland basin to the evolving Banda orogen. In: P.A. Allen & P. Homewood (eds.) Foreland Basins, Int. Assoc. Sedimentologists (IAS), Spec. Publ. 8, p. 91-102.

Audley-Charles, M.G. (1986)- Rates of Neogene and Quaternary tectonic movements in the Southern Banda arc based on micropalaeontology. J. Geol. Soc. London 143, p. 161-175.
(Outer Banda Arc composed of highly deformed sediments that accumulated at Australian continental margin. Dating of onset of folding/uplift of Timor, from deep submarine position at end Neogene nappe emplacement, to mountains now 3 km high, indicates post-collision uplift rate initially 3 mm/yr, then slowed to ~1.5 mm/yr. Where Australian continental margin meets E end of present Java Trench Australian margin has overridden Trench in Timor region by 240 km. After nappe emplacement shortening of continental crust migrated towards Australian continent and shelf became involved in imbrication with shortening of cover rocks between nappes and present shelf edge amounting to ~40 km during last 2 Ma)

Audley-Charles, M.G. (1990)- Triassic Aitutu Formation of Timor, Indonesia. In: Triassic biostratigraphy and paleogeography of Asia, ESCAP Atlas of Stratigraphy IX, Min. Res. Dev. Ser. 59, U.N., New York, p. 11-15.
(Shortened version from Audley-Charles (1968). Due to structural complexity and generally poor fossils, hard to do detailed stratigraphic studies. Deep marine Carnian- Norian Aitutu Fm thickness ~1000m, probably unconformable over Permian limestones. Basal series dark Tallibellis Mb mudstones, probably Norian age, overlain by Aitutu Fm radiolarian calcilutites (80%)/ shales (15%)/ calcarenites (5%), radiolarites, bituminous rocks with Halobia and Daonella. Top Aitutu Fm unconformable below E Jurassic Wai Luli Fm)

Audley-Charles, M.G. (2011)- Tectonic post-collision processes in Timor. In: R. Hall et al. (eds.) The SE Asian gateway: history and tectonics of Australia-Asia collision, Geol. Soc. London, Spec. Publ. 355, p. 241-266.
(Australian continental margin collided with Asian fore-arc at 4 Ma, transforming Banda Trench into Timor fold-thrust belt. Tectonic Collision Zone (TCZ) progressively filled by two Australian continental upper crust mega-sequences. Slowing subduction of Australian sub-crustal lithosphere after ~2.5 Ma led to uplift of TCZ that raised Timor 3 km above sea level. Asian Banda fore-arc deformation linked to ~30 km SE-wards rollback of subducting Australian lithosphere. Two Asian fore-arc nappes (Banda, Aileu-Maubisse) thrust S-wards from Banda fore-arc onto older of two highly deformed Australian continental margin upper crust mega-sequences. Wetar Suture created as thrust at base of Australian partially detached continental lower crust propagated into Asian fore-arc)

Audley-Charles, M.G. & A.J. Barber (1976)- The significance of the metamorphic rocks of Timor of the Banda arc, Eastern Indonesia. Tectonophysics 30, p. 119-128.
(All metamorphic rocks in Timor allochthonous. Three groups: lustrous slate, amphibolite-serpentinite, and granulite-amphibolite-greenschist complex. Granulite facies meta-anorthosite in Timor must have originated near continental mantle-crust boundary and may represent slices of ancient Asian continental basement. Metamorphic rocks of Seram remarkably similar to those of Timor. Overthrust directions of metamorphic rocks in Timor is S-ward, in Seram N-ward. Opposite thrusts may be explained in terms of Banda Arc acquiring sinuosity after emplacement of metamorphic rocks)

Audley-Charles, M.G., A.J. Barber & D.J. Carter (1979)- Geosynclines and plate tectonics in Banda Arcs, Eastern Indonesia: Discussion American Assoc. Petrol. Geol. (AAPG) Bull. 63, p. 249-252.
(Discussion of Crostella (1977) paper on Timor geology)

Audley-Charles, M.G. & D.J. Carter (1972)- Palaeogeographical significance of some aspects of Palaeogene and Early Neogene stratigraphy and tectonics of the Timor Sea region. Palaeogeogr. Palaeoclim. Palaeoecology 11, p. 247-264.

(‘Autochthonous’ Early Miocene Cablac limestones unconformable on folded Early Eocene carbonates, which unconformably overlie metamorphic schists, implying Paleocene and ?Late Eocene- Oligocene? orogenic phase on Timor. Four Eocene facies on Timor, incl. Late Eocene limestones with Pellatispira and deep-water facies and volcanoclastics, all different from NW Australian Shelf and Timor Trough, where most of Tertiary is deepwater carbonate. Cretaceous- M Miocene paleogeography)

Audley-Charles, M.G. & D.J. Carter (1974)- Petroleum prospects of the southern part of the Banda Arc, eastern Indonesia. Comm. Co-ord. Joint Prospecting Mineral Resources in Asian Offshore Areas (CCOP), Techn. Bull. 8, p. 55-70.
(Mainly overview of geology of Timor, with comments on oil seeps and prospectivity of island)

Audley-Charles, M.G. & R. Harris (1990)- Allochthonous terranes of the Southwest Pacific and Indonesia. Philos. Trans. Royal Soc. London 331, p. 571-587.
(Timor is deformed Australian margin, overridden by allochthonous nappes. Lowest is ‘Lolotoi metamorphics’- ‘Palelo Arc’ (basal metamorphics, Cretaceous-Eocene arc volcanics and marine sediments, unconformably overlain by mid-Eocene-Early Miocene carbonates; similar succession in Sumba; thrusted over Australian margin in latest Miocene). Second exotic terrane is Maubisse Permo-Triassic limestone with pillow basalts; supposedly most distal part of rifted Australian margin. Third terrane is ‘supra-subduction zone’ Ocussi ophiolite, now being thrust over N Timor margin)

Audley-Charles, M.G. & R. Harris (1990)- Allochthonous terranes of the Southwest Pacific and Indonesia. Philos. Trans. Royal Soc. London A331, p. 571-587.
(Mainly on Timor island. Deformed Australian margin, overridden by three allochthonous nappes)

Audley-Charles, M.G. & J.S. Milsom (1974)- Comment on ôPlate convergence, transcurrent faults, and internal deformation adjacent to southeast Asia and the western Pacificö. J. Geophysical Research 79, 32, p. 4980-4981.
(online at: http://searg.rhul.ac.uk/pubs/audley-charles_milsom_hamilton_1974%20discussion%20of%20Fitch%20Weber%20deep.pdf)
(A&M suggest Timor Trough and its eastward extensions are 'downbuckle in continental crust, with limited underthrusting', not surface trace of subduction zone. See also reply by Fitch and Hamilton (1974), who still do interpret this as subduction zone that continues East uninterrupted from Java Trench, based in part on Shell Group seismic profiles across N side of Timor Trough showing large-scale S-ward directed overthrusts and imbrications)

Aulia, D., S.H. Sinaga, R. Adiarsa, F. Alôayubie, I.B. Arindra, F. Nikmata & I. Rodelian (2011)- Petrology and provenance of sandstone from Mesozoic sequence Soe-Kapan Block, West Timor, NTT. Proc. 35th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA11- SG-034, 12p.
(Sandstones (lithic arenites) from Soe-Kapan Block, SW Timor: Permian Bisane Fm (quartz 45-57%, feldspar 9-13%, lithic fragments 9-19% (andesite, diorite, carbonate, sandstone, chert, schist and phyllite) and Triassic Aitutu Fm (quartz 31-72%, feldspar 9-39%, lithics 5-21%). Most likely provenance recycled orogen. Flute casts in Aitutu Fm indicate dominant NW to SE transport directions)

Bachri, S. (1995)- The origin of the Aileu and Maubisse Formations in the East Timor area, Indonesia. In: J. Ringis (ed.) Proc. 31st Sess. Comm. Co-ord. Joint Prospecting Mineral Resources in Asian Offshore Areas (CCOP), Kuala Lumpur 1994, 2, p. 232-241.
(Aileu Fm metamorphics at N coast of E Timor decrease in metamorphic grade in S direction and grade into both Permian Maubisse Fm and Jurassic Wai Luli Fm, suggesting it is composed of metamorphosed Permian and Jurassic NW Australian passive margin sediments)

Bachri, S. (2004)- The relationships between the formation of the multi-genesis chaotic rocks and the Neogene tectonic evolution in Timor. J. Sumber Daya Geologi 14, 3, p. 94-100.
(Chaotic rocks of Bobonaro Complex of Timor occupy 40% of Timor island. Composed of scaly matrix with exotic blocks of Permian- Quaternary(?) age. Scaly clay matrix rich in deep marine foraminifera, varying in age from Triassic, Mesozoic and Late Cretacous. Generated in multiple ways: mainly sedimentary olistostrome,

less common tectonic melange and shale diapirs. Tectonic melange formed since N-dipping subduction in Paleogene. Arc-continent collision since E Neogene, with shale diapirs and olistostrome at beginning of collision. Olistostrome may have covered most of tectonic melange, which is probly older. After subduction ceased in post-Neogene shale diapirism continued)

Bachri, S. (2008)- Formasi Maubisse dan Aileu di bagian Barat Timor Leste dalam kerangka tektonostratigrafi Pulau Timor. J. Sumber Daya Geologi 18, 5, p. 281-289.
(online at: http://jgsm.geologi.esdm.go.id/index.php/JGSM/article/view/254/234)
('The Maubisse and Aileu Formations in the west of East Timor, in the framework of Timor tectonostratraphy'. Position of Maubisse and Aileu Fms in Timor Leste controversial, but tendency to place them in para-autochthonous sequence. Formations transitional relationships with overlying para-autochthonous Wailuli Fm. Paleontological evidence indicates Maubisse Fm derived from Australian continent, and related Aileu Fm was located on NW flank of Australia until Neogene arc-continent collision event)

Bachri, S. (2011)- Tektonostratigrafi Busur Banda dengan referensi bagian barat Timor Leste dan bagian timur Pulau Seram. J. Sumber Daya Geologi 21, 2, p. 53-62.
(online at: http://jgsm.geologi.esdm.go.id/index.php/JGSM/article/view/135/132)
('Tectonostratigraphy of the Banda Arc, with reference to the western part of Timor Leste and the eastern part of Seram'. Timor and Seram similar parts of Banda Outer Arc collision zone between Australia NW Shelf and Banda Arc subduction system. Three tectonostratigraphic sequences of differents origins: (1) para-autochthonous sequence, derived from Australia; (2) Banda forearc sequence (allochthonous sequence), nappe structures overthrust on para-autochthonous sequence; (3) autochthonous sequence unconformably over previous sequences. Bobonaro olistostrome unit of Timor Island can be compared with Salas Complex on Seram. Lolotoi metamorphic complex on Timor Island can be correlated with Kobipoto Complex on Seram Island, forming basement of para-autochthonous sequence)

Bachri, S., B. Hermanto & E. Partoyo (1995)- Genesa kompleks Bobonaro di Timor Timur. J. Geologi Sumberdaya Mineral 5, 45, p. 17-22.
('Genesis of the Bobonaro Complex in East Timor'. Bobonaro Complex of Timor multiple genesis:(1) mainly deep marine M Pliocene olistostromal deposits, (2) minor tectonic melange, and (3) minor part formed by shale diapirism and mud volcano activity. Matrix with planktonic foraminifera suggest age range within Late Miocene- E Pliocene (zones N14-N19) and in deep marine setting based on benthic foraminifera like Planulina wuellerstorfi, Favocassidulina, etc. Overlying Viqueque Fm marls with Late Pliocene- E Pleistocene (N21-N22) planktonics)

Barber, A.J. & M.G. Audley-Charles (1976)- The significance of the metamorphic rocks of Timor in the development of the Banda Arc, eastern Indonesia. Tectonophysics 30, p. 119-128.
(All metamorphic massifs on Timor are allochthonous. Various grade metamorphic rocks on Timor. Three distinct metamorphic grade groups: lustrous slate, amphibolite-serpentinite and granulite- amphibolite-greenschist complex. Highest grade metamorphic rocks (granulite facies) in Booi massif. Amphibolite facies in many massifs through Timor. Many high-grade metamorphic rocks affected by subsequent lower grade (greenschist) metamorphism. High-grade metamorphic rocks interpreted as fragments of ancient continental crust, perhaps from Asia/ Sundaland)

Barber, A.J., M.G. Audley-Charles & D.J. Carter (1977)- Thrust tectonics in Timor. J. Geol. Soc. Australia 24, p. 51-62.
(Reply to Grady (1975) who argued structure of Timor can be interpreted without major overthrusting. Reasons for major overthrusting restated here and tied to collision between Australian continental margin and detached portion of Asiatic continental margin. Timor is series of overlapping thrust slices, resting on folded sediments of Australian continental shelf. Kolbano lowest thrust sheet, composed of deformed deep-water calcilutites. Followed to N by Lolotoi thrust sheet (metamorphics with unmetamorphosed ophiolites, clastic sediments and massive Miocene limestones). Overlying this group to N is Maubisse-Aileu thrust sheet (with Permian crinoidal limestones and volcanics in S, passing N into shales and sandstones, with increase in deformation and metamorphism from S to N. Slates in S pass into amphibolite facies on N coast of E Timor. A further thrust-slice composed of ophiolites rests on this thrust unit on N coast of W Timor between Wini and Atapupu. Mesozoic cherts sandwiched between metamorphic thrust sheets and 'autochthonous' Bisane Fm Permian clastics suggest ocean floor separated this from Maubisse Fm Permian carbonates)

Barber, A.J. & K. Brown (1988)- Mud diapirism: the origin of melanges in accretionary prisms? Geology Today 4, p. 89-94.
(Chaotic melange deposits, mixed blocks in clay matrix, commonly attributed to submarine slumping, but in accretionary complexes shale diapirism produces large volumes of melange. With examples from Timor mud volcanoes and associated deposits of Bobonaro scaly clay with blocks)

Barber, A.J., S. Tjokrosapoetro & T.R. Charlton (1986)- Mud volcanoes, shale diapirs, wrench faults and melanges in accretionary complexes, Eastern Indonesia. American Assoc. Petrol. Geol. (AAPG) Bull. 70, p. 1729-1741.
(Timor mud volcanoes. Bobonaro scaly clay commonly interpeted as melange or olistostrome, but more likely product of shale diapyrism)

(Biostrat of 76 outcrop samples collected by Timor Oil Co in Timor Leste. Oldest rocks with Permian foraminifera and one sample with mollusc Atomodesma exarata. Tertiary samples M-U Eocene (with Nummulites and planktonics and reworked U Cretaceous plankton), Lower Miocene (Te with Spiroclypeus and reworked U Cretaceous Globotruncana limestone) and pelagic U Miocene (more likely Plio-Pleistocene; JTvG). Also several samples rich in radiolaria, probably Mesozoic. No locality maps))

Belford, D.J. (1961)- Micropalaeontology of samples from Portuguese Timor. Bureau Mineral Res., Canberra, Record 1961/6, p. 1-5.
(online at: www.ga.gov.au/products/servlet/controller?event=GEOCAT_DETAILS&catno=10733)

(Biostrat of 56 outcrop samples collected by Timor Oil Co. Oldest samples are of Permian age (foraminifera). Radiolarian-rich sediments are probably of Triassic age (probable Halobia). Also Eocene limestone with Alveolina and planktonics-rich U Miocene sediments (more likely Pliocene?; JTvG; one sample with reworked Permian). No locality maps)

Belford, D.J. (1961)- Micropalaeontology of samples from Matai No. 1 bore, Portuguese Timor. Bureau Mineral Res., Canberra, Record 1961/31, p. 1-3.
(online at: www.ga.gov.au/products/servlet/controller?event=GEOCAT_DETAILS&catno=10758)
(Summary of biostratigraphy of Matai 1 cuttings (370'- 2000'). Interval 370-760' regarded as 'block clay' of Upper Miocene age (but faunal lists include Pleistocene Gr. truncatulinoides and Hyalinea balthica; JTvG) with reworked Upper Cretaceous and Eocene forams. Eocene limestone with Discocyclina and Alveolina rel. common at 760-830'. Also limestone chips between 880-1000' with Late Eocene Discocylina and Pellatispira, but not sure if in situ. Sample gap between 1040-1300', and no microfossils observed between 1300-2000')

Benincasa, A. (2009)- The geology of Mount Mundo Perdido, Timor Leste. Thesis University of Western Australia, Perth, p. 1-169. *(Unpublished)*
(Mt Mundo Perdido 1750m high massif, originally interpreted as coherent block of Lower Miocene Cablac Limestone, but is complex of rock types of different ages and tectonostratigraphic affinities, including 'Gondwanan affinity' Triassic-Jurassic carbonates, Cretaceous- Oligocene pelagites (pink-white Cretaceous, red shaly Eocene), 'Banda-Terrane' earliest Miocene limestones on Barique Fm mafic island arc volcanics and associated with gabbros and schists, and Plio-Pleistocene synorogenic(?) deposits. Dominant structures late stage, high-angle, oblique-slip faults, probably in sinistral strike-slip zone)

Benincasa, A. (2015)- The 'fatus' of East Timor: stratigraphy and structure. Ph.D. Thesis University of Western Australia, Perth, p. 1-504.
(online at: http://research-repository.uwa.edu.au/files/5338890/Benincasa_Aaron_2015.pdf)
(Studies of isolated limestone peaks ('fatus') of Timor Leste, incl. Mt Mundo Perdido, Laritame, Builo, Bibileu, Paitchau, Matebian, etc. Many previously mapped as mainly Miocene Cablac Lst, but cores of all fatus contain Late Triassic- E Jurassic shallow water limestones associated with Triassic- Jurassic rift deposits, Cretaceous-Oligocene pelagic limestones, Asian-affinity Tertiary limestones and volcanics, etc. Many fatus are pop-up structures, with recent high-angle oblique slip and strike-slip faults (map suggests all are associated with Banda Terrane?))

Benincasa, A., M. Keep & D. Haig (2012)- A restraining bend in a young collisional margin: Mount Mundo Perdido, East Timor. Australian J. Earth Sci. 59, 6, p. 859-876.
(With Appendix 1 online at: www.gsa.org.au/pdfdocuments/AJES_Supplementary%20Papers/59-6%20supp%20papers_Benincasa%20et%20al%20AJES%20.pdf)
(Mt Mundo Perdido 1 km NW of Ossu. Like Mt Cablac, originally mapped as Miocene 'Cablac Lst', but has core of highly deformed (Late Triassic?)- E Jurassic oncoidal- ooid limestone, overlain by bathyal latest Jurassic- E Cretaceous calpionellid/ Inoceramus wackestone and mid-Cretaceous-Oligocene pelagic limestones. It is surrounded (looks like overlain?; JTvG) by less-deformed latest Oligocene- earliest Miocene (N4) Booi Limestones and Pleistocene bathyal limestones. Structure dominated by high angle, oblique-slip and strike-slip faults that were active into Pleistocene, comparable to pop-up structures at restraining bends within E-W zone of sinistral strike-slip. Appendix 1 documents E Jurassic age of 'Perdido Limestone' algal limestone (incl. Thaumatoporella ?parvovesiculifera and agglutinated forams (Siphovalvulina, Duotaxis))

Berry, R.F. (1979)- Deformation and metamorphism of the Aileu Formation, East Timor. Ph.D. Thesis, School of Earth Sciences, Flinders University of South Australia, p. 1-393.
(online at: http://eprints.utas.edu.au/11496/2/Whole-Berry,_R.F.,_PhD_(Flinders),_1979.pdf))
(Aileu Fm along N coast of E Timor composed of metamorphosed shales, siltstones and arenites with minor limestones and basites. Greater proportion of coarser and quartz-rich sediment towards N coast. Fossils rare, dominated by crinoid ossicles, probably Permian age. Metamorphic grade lower greenschist facies in SW, almandine-amphibolite facies in NE. Amphibolite and schists with marble close in composition to Permian Maubisse Fm. On N coast of E Timor is Hili Manu peridotite, faulted against Aileu Fm in S; lherzolite and

serpentinite abut Aileu Fm at highest metamorphic grade (p. 239). Five structural phases recognised. K/Ar ages of hornblendes from amphibolites 7.7- 16.5 Ma, mean 11.3 Ma. Geology of Timor consistent with evolution as rift valley in Late Paleozoic-Early Mesozoic and trailing margin from Cretaceous- E Miocene, Late Miocene arc-continent collision followed by uplift and minor Plio-Pleistocene deformation)

Berry, R.F. (1981)- Petrology of the Hili Manu lherzolite, East Timor. J. Geol. Soc. Australia 28, 4, p. 453-469.
(Spinel lherzolite outcrop on N coast of E Timor. Most common rock-type clinopyroxene-poor lherzolite, but also clinopyroxene-rich lherzolite and harzburgite. Three events indicated by geothermometry (1) coarse exsolution lamellae of orthopyroxene in clinopyroxene porphyroclasts (1250°C); (2) granoblastic texture equilibrated at 1100°C; and (3) rocks mylonitised at 800-1000°C. Peridotite probably oceanic upper mantle trapped between Java Trench and Inner Banda Arc)

Berry, R.F., C. Burrett & M. Banks (1984)- New Triassic faunas from East Timor and their tectonic significance. Geologica et Palaeontologica 18, p. 127-137.
(Conodonts from red ammonoid-bearing limestone 6 km W of Manatuto, previously assigned to Permian Maubisse Fm, contains Upper Smithian (E Triassic), Tethyan conodonts. Area previously interpreted as thrusted, with inverted ages (Permian on Triassic), but probably simple Triassic stratigraphic succession and structure mainly steeply dipping normal faults. Conodonts well-preserved with CAI of 1, suggesting rel. low paleotemperatures <100°C)

Berry, R.F. & A.E. Grady (1981)- Deformation and metamorphism of the Aileu Formation, North coast, East Timor and its tectonic significance. J. Structural Geol. 3, p. 143-167.
(Aileu Fm at N coast of Timor probably metamorphosed Permian (+ Jurassic?) flysch. Metamorphism increasing from low greenschist facies in SW to upper amphibolite facies in E. Five deformation phases; second phase post-dates metamorphic maximum (Jurassic?), produced tight folds and may be Late Miocene. Metamorphic maximum occurred before 11 Ma)

Berry, R.F. & A.E. Grady (1981)- The age of the major orogenesis in Timor. In: A.J. Barber & S. Wiryosujono (eds.) The geology and tectonics of Eastern Indonesia. Proc. CCOP-IOC Working Group Meeting, Bandung 1979, Geol. Res. Dev. Centre (GRDC), Bandung (GRDC), Spec. Publ. 2, p. 171-181.
(Radiometric dates of N coast E Timor Aileu Fm metamorphic rocks suggest metamorphism peak before Late Miocene (8-9 Ma; possibly even before 70 Ma; Harris & Long 2001), with most intense deformation probably between 11-6 Ma)

Berry, R.F. & G.A. Jenner (1982)- Basalt geochemistry as a test of the tectonic models of Timor. J. Geol. Soc. 139, 5, p. 593-604.
(Geochemistry of metamorphosed Permo-Triassic basic volcanics on Timor from both 'allochthonous' and parautochthonous' formations are all consistent with rift or ocean floor setting; no calc-alkaline arc volcanics)

Berry, R.F. & I. McDougall (1986)- Interpretation of 40Ar/39Ar and K/Ar dating evidence from the Aileu Formation, East Timor, Indonesia. Chemical Geology 59, p. 43-58.
(Aileu Fm-Maubisse metamorphics retrograde metamorphism (=collision?) at 8 Ma. Cooling to 300°C by 5.5 Ma)

Berry, R., J. Thompson, S. Meffre & K. Goemann (2016)- U-Th-Pb monazite dating and the timing of arcï continent collision in East Timor. Australian J. Earth Sci. 63, 4, p. 367-377.
(Metamorphic age of highest-grade rocks formed in Timor arc-collision collision remains controversial. U-Th-Pb dating of monazite from Aileu Fm amphibolite-grade schists suggests peak metamorphism at 5.5-4.7 Ma)

Beyrich, E. (1862)- Gebirgsarten und Versteinerungen von Koepang auf Timor. Zeitschrift Deutschen Geol. Gesellschaft 14, p. 537.
(online at: https://archive.org/details/zeitschriftderd141862deut)
('Mountain types and fossils from Kupang on Timor'. First brief note on Late Paleozoic fossils of Timor (brachiopods, crinoids), collected by Dr. Schneider and being studied by Beyrich))

Beyrich, E. (1865)- Uber eine Kohlenkalk-Fauna von Timor. Abhandl. Konigl. Akad. Wissensch. Berlin, 1864, p. 59-98.
('On a Carboniferous fauna from Timor'. First description of 'Carboniferous' (now accepted as Late Permian) limestone fauna from Timor, collected in Kupang area by Dr. Schneider. Includes mollusc genus Atomodesma, solitary rugose coral Zaphrentis, new brachiopod species Spirifer kupangensis (= Arcullina; Waterhouse 2004), Rhynchonella timorensis (assigned to Uncinunellina timorensis by later authors; JTvG), etc.)

Bird, P.R. (1987)- The geology of the Permo-Triassic rocks of Kekneno, West Timor. Ph.D. Thesis, University of London, p. 1-264. *(Unpublished)*
(Structure, stratigraphy and sedimentology of 'parautochthonous' mainly fine clastic Permo-Triassic in Kekneno area. Sandstone petrography shows Timor Permian sands less mature than those of NW Shelf of Australia. Paleocurrents mainly towards WSW, suggesting source from E (Arafura) and/or N (terrane removed in Jurassic rifting), not from NW Shelf. Slice of Banda fore-arc basement obducted over parautochthonous, with fossiliferous Permian Maubisse carbonates and volcanics very different from parautochton)

Bird, P.R., K. Brata & I. Umar (1989)- Sedimentation and deformation of the Permo-Triassic of Kekneno, West Timor: from intracratonic basin to accretionary complex. In: B. Situmorang (ed.) Proc. 6th Regional Conf. Geology mineral and hydrocarbon resources of SE Asia (GEOSEA VI), Jakarta 1987, IAGI, p. 3-23.
(Permian and Triassic turbiditic marine clastics in Kekneno area of Timor considered deposited in intra-cratonic basin near NW margin of Gondwana. Thickness hard to estimate due to common imbrication along mainly N-dipping thrust planes. Oldest formation Atahoc Fm, >600m thick, with common ammonites of Sakmarian Properrinites zone; in E with pillow lavas near top. Overlain by Kungurian Cribas Fm with Atomodesma, 400m thick, current ripple directions to SE. Sandstones petrologically much less mature than age-equivalent rocks of NW Australia Shelf, indicating Timor sediments not derived from Australian hinterland. Paleocurrents show sediment transport predominantly to WSW secondary transport to SE. Northerly source removed by Jurassic rifting. Kekneno Permo-Triassic overthrusted by Mutis allochthon (W-ward thrusting?))

Bird, P.R. & S.E. Cook (1991)- Permo-Triassic successions of the Kekneno area, West Timor: implications for palaeogeography and basin evolution. J. Southeast Asian Earth Sci. 6, 3-4, p. 359-371.
(Permian sandstones less mature and different heavy mineral assemblages from Bonaparte/Timor Sea equivalents. This and Permian paleocurrent data suggests mainly northerly provenance of Timor Permian. Late Triassic Babulu Fm turbidites dominant sediment transport directions NE to SW or E to W)

Bless, M.J.M. (1987)- Lower Permian ostracodes from Timor (Indonesia). Proc. Kon. Nederl. Akademie Wetenschappen, Amsterdam, B, 90, 1, p. 1-13.
(Lower Permian (Sakmarian- Artinskian) ostracodes from Bitauni, Mutis, Nono Ofien and Noil Toensieh in W Timor. Diverse 'Thuringian-type' assemblages with 40 species, usually interpreted as deep marine, as also suggested by Grundel & Kozur 1975)

Tectonic accretion where decollement steeper than outer trench slope, tectonic erosion where decollement shallower than outer slope dip. Applied to Timor Trough to demonstrate subduction has ceased)

Charlton, T.R. (1989)- Geological cross-section through the Timor collision complex, Eastern Indonesia. In: B. Situmorang (ed.) Proc. 6th Regional Conf. Geology mineral hydrocarbon resources of Southeast Asia (GEOSEA VI), Jakarta 1987, IAGI, p. 93-104.
(Cross-section across Timor collision zone with characteristics of subduction-accretion complex, but Timor Trough subduction trench has recently become inactive. Plate convergence being transferred to young zone of thrusting N of volcanic arc, with reverse sense of polarity. Accretionary complex morphology modified by sinistral wrench faulting. Kolbano area thrust-bounded repetitions of Cretaceous- Miocene of sediments accumulated at outermost edge of Australian NW Shelf (up to 9 imbricates onshore?))

Charlton, T.R. (1989)- Stratigraphic correlation across an arc-continent collision zone: Timor and the Australian Northwest Shelf. Australian J. Earth Sci. 36, p. 263-274.
(Facies of Triassic- Neogene series of imbricate stack of Kolbano foldbelt, SW Timor, is deep to very deepwater, suggesting it represents outermost edge of pre-collisional Australian margin. Similarities include ?Early Jurassic redbeds, Oxfordian 'breakup unconformity' with Early Cretaceous missing, etc. Implication is that N Timor is either block that rifted off Australia, then collided in Pliocene (Barber 1979) or partly rifted marginal plateau off NW shelf)

Charlton, T.R. (2001)- The petroleum potential of West Timor. Proc. 28th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, p. 303-317.
(Timor island has numerous oil and gas seeps, and contains high-quality hydrocarbon source rocks, but island widely considered to have only moderate petroleum potential due to its structural complexity, but complexity is limited to shallow structural levels, and below this simpler structural style predominates. Kolbano area of SW Timor interpreted to be underlain by large, simple inversion anticline. Banli-1 penetrated flank of this structure, below prospective crest)

Charlton, T.R. (2002)- The petroleum potential of East Timor. Australian Petrol. Prod. Explor. Assoc. (APPEA) J. 42, p. 351-369.
(Hydrocarbon prospectivity of E Timor widely considered to be only moderate due to Timor island's complex structure, but here interpreted as having higher potential in large, simple inversion structures below shallow complexly folded thrust/ melange terain)

Charlton, T.R. (2002)- The structural setting and tectonic significance of the Lolotoi, Laclubar and Aileu metamorphic massifs, East Timor. J. Asian Earth Sci. 20, 7, p. 851-865.
(Two types of metamorphic complexes on Timor: (1) Australian continental basement (Lolotoi, Lachlubar), (2) allochthonous basement derived from Banda forearc (Mutis in W Timor, Aileu in E Timor; with inverted metamorphic gradients))

Charlton, T.R. (2003)- The petroleum potential of sub-thrustbelt inversion anticlines in the Banda forearc. Indon. Petroleum Assoc. (IPA) Newsl., March 2003, p. 22-27.

Charlton, T.R. (2004)- The petroleum potential of inversion anticlines in the Banda Arc. American Assoc. Petrol. Geol. (AAPG) Bull. 88, 5, p. 565-585.
(Mainly on structural style of Timor. Banda forearc is fold- thrust belt, with imbricated outer edge of Australian continent, overlain locally by fragments of precollisional oceanic forearc, and is established petroleum province in Seram. Structural complexity overstated. Basement-involved inversion structures in deeper parts of collision complex. Inverted graben basins filled with Permian-Jurassic continental margin sequences, including Late Triassic- E Jurassic source rocks and potential reservoirs, sealed by M-L Jurassic shales. Jurassic shales decollement separates shallow-level structural complexity from deeper simpler structural style of large inversion anticlines)

Charlton, T.R., A.J. Barber & S.T. Barkham (1991)- The structural evolution of the Timor collision complex, Eastern Indonesia. J. Structural Geol. 13, 5, p. 489-500.
(New Timor structural evolution model combining element of previous three Timor models; foldbelt as rel. simple progressive thrusting of Australian crustal elements, starting in N at 8 Ma)

Charlton, T.R., A.J. Barber, R.A. Harris, S.T. Barkham, P.R. Bird, N.W. Archbold, N.J. Morris, R.S. Nicoll, H.G. Owen, R.M. Owens, J.E. Sorauf, P.D. Taylor, G.D. Webster & J.E. Whittaker (2002)- The Permian of Timor: stratigraphy, palaeontology and palaeogeography. J. Asian Earth Sci. 20, p. 719-774.
(Extensive compilation of Timor Permian stratigraphy and paleontology, with specialist reviews of brachiopods, bryozoans, cephalopods, conodonts, corals, echinoderms, foraminifera, molluscs, trilobites, etc. Permian sequences deposited on Australian continental basement which was undergoing extension, with basaltic volcanism. Carbonates of Maubisse Fm deposited on horst blocks and volcanic highs, clastic sediments of Atahoc and Cribas Fms deposited in grabens)

Charlton, T.R., A.J. Barber, A.J. McGowan, R.S. Nicoll, E. Roniewicz, S.E. Cook, S.T. Barkham & P.R. Bird (2009)- The Triassic of Timor: lithostratigraphy, chronostratigraphy and palaeogeography. J. Asian Earth Sci. 36, p. 341-363.
(Overview of Triassic successions of Timor, exposed in fold-and-thrust belt and melange complex. Three formal lithostratigraphic units defined previously (Niof, Aitutu and Babulu Fms), with a fourth, Wai Luli Fm, primarily Jurassic in age but extending down into Triassic. Triassic extension not associated with major volcanism, unlike Early Permian extension)

Charlton, T.R. & D. Gandara (2012)- Structural-stratigraphic relationships at the boundary of the Lolotoi Metamorphic Complex, Timor-Leste: field evidence against an allochthonous origin. First Int. Geological Congress of Geology of Timor-Leste, Dili 2012, p. 41-44. *(Extended Abstract)*
(Results of new fieldwork at several Lolotoi Complex massifs ofTimor Leste suggests Australian continental basement origin for complex. S front of Lolotoe metamorphic massif controlled primarily by down-to-S normal faults, not N-dipping thrust front, and metamorphics extend to depth of 2805m at TD in Cota Taci-1 well, Suai

Basin. Stratigraphic contacts observed between Lolotoi Complex and Eocene Dartollu Fm, but also between Lolotoi Compex and Permian Maubisse Fm. One outcrop of Dartollu Fm with reworked fragments of Maubisse Fm crinoid limestone clasts and porphyritic volcanics. Similar relationships at Legumau Range)

Charlton, T.R. & D. Gandara (2014)- The petroleum potential of onshore Timor-Leste. Proc. 38th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA14-G-017, 7p.
(Brief review of petroleum prospectivity in Mesozoic of 6 areas of onshore Timor Leste. Two new lithostratigraphic units recognized: (1) Foura Sst, thick-bedded but fine-grained sandstone of probable E Jurassic age; appears to interdigitate with shales of Wai Luli Fm and possibly correlative to 'Plover Sst' in Banli 1 well of SW Timor; (2) Late Jurassic Tchinver Shale, 100-200m thick shale section, with Belemnopsis-type belemnites, disconformably over shales-thin sandstones of Wai Luli Fm; with source rock/seal potential)

Charlton, T.R., D. Gandara & N. da Costa Noronha (2017)- TIMOR GAPȏs onshore Block: a preliminary assessment of prospectivity in onshore Timor-Leste. In: SEAPEX Exploration Conference 2017, Singapore, Session 4, 30p. *(Abstract + Presentation)*
(Onshore block in SW part of Timor Leste now held by national oil company Timor Gap EP. 18 exploration wells drilled between 1960-1973: ten with hydrocarbons, two (Matai-1/-1A and Cota Taci-1) tested oil in subcommercial quantities. At least 37 surface hydrocarbon seeps (14 oil, 23 gas) across block. Gas from seeps both high-mature thermogenic (from Permian?) and biogenic. Triassic calcareous restricted marine shale likely source for all Timor oils. Likely subthrust inversion anticlines of Permo-Triassic rifts)

Charlton, T.R., D. Gandara, D. Freitas, M. Guterres & N. da Costa Noronha (2018)- TIMOR GAPȏs onshore Block: a preliminary assessment of prospectivity in onshore Timor-Leste. In: PEGSB SEAPEX Asia Pacific E&P Conference, London, 8p.
(Review of 3 onshore oil exploration blocks in SW Timor Leste: A- Suai (Suai Late Miocene - Recent syn-orogenic basin in 'Banda Terrane' basement), C- Betano-Same, and Block B)

Charlton, T.R. & Suharsono (1990)- Mesozoic-Tertiary stratigraphy of the Kolbano area, southern West Timor. Bull. Geol. Res. Dev. Centre (GRDC), Bandung 14, p. 38-58.
(Kolbano complex interpreted as accretionary complex. Late Jurassic- Miocene accumulated on outermost edge of Australian NW Shelf. Possible unconformity at base Ofu Fm deepwater marls, with Eocene planktonics but also abundant reworked Cretaceous and Paleocene planktonics)

Charlton, T.R. & D. Wall (1994)- New biostratigraphic results from the Kolbano area, southern West Timor: implications for the Mesozoic-Tertiary stratigraphy of Timor. J. Southeast Asian Earth Sci. 9, p. 113-122.
(On Kolbano area Late Jurassic- Neogene stratigraphy and dinoflagellate, forams, nannofossil contents of selected samples. Youngest sediments involved in Kolbano foldbelt thrusting N18-N19/20, latest Miocene-earliest Pliocene (but nothing younger than N15 suggested by Keep and Haig 2010))

Chiang, H.W., R.A. Harris, C. Prasetyadi, C.C. Shen, T.C. Chiu, N.L. Cox & Y.G. Chen (2010)- Th-230 dates of MIS 5e coral terraces in Kisar Island, Eastern Indonesia. EGU General Assembly, Vienna, Conf. Abstracts 12, p. 13467.
(online at: http://adsabs.harvard.edu/abs/2010EGUGA..1213467C)
(New 230Th dates raised Quaternary coral terraces at Kisar suggest ages of ~122 ka and minimum uplift rate of 0.1 m/kyr On N coast of Timor-Leste MIS 5e terraces reach 55m high, with uplift rate of ~0.4 m/kyr. No remnant Holocene fringe reefs around Kisar Island, also suggesting rel. low activity tectonics at Kisar)

Clowes, E. (1997)- Micropalaeontological analysis of the Kolbano sequence (Jurassic to Pliocene), West Timor and its radiolarian fauna. Ph. D. Thesis, University College London, London, p. 1-443. *(Unpublished)*
(Detailed descriptions of SW Timor Kolbano foldbelt Early Cretaceous- E Miocene radiolarian-rich deep-water pelagic facies. Nakfunu Fm dated as Valanginian-Aptian. Albian-Coniacian hiatus. Ofu Fm mainly Santonian-Maastrichtian. Early Cretaceous species dominated by endemic species known only from high S latitudes, but Tethys species present as well. Aptian-Albian more common Tethys species)

(With palynogy analyses by R. Helby)

Da Costa Monteiro, F., J.A. Grant-Mackie, B. Ricketts & B. Woods (2003)- Some Late Triassic rocks in Timor Leste. In: Int. Conf. Opportunities and challenges for oil & gas & mining sectors in Timor-Leste, Dili 2003, 31p.

Da Costa Monteiro, F., B. Ricketts, J.A. Grant-Mackie & B. Woods (2002)- Late Triassic strata from East Timor- stratigraphy, sedimentology and hydrocarbon potential. Geol. Soc. New Zealand, Ann. Conf. Abstracts, p. 17.
(E Timor Late Triassic flysch-like interbedded sandstone- shale in lower part; upper part mainly calcarenites, massive sandstones and polymict conglomerates. Locally, Wailuli Fm, a name applied to E-M Jurassic rocks based on ammonites and belemnites, extends down into Late Triassic. Much of Wailuli Fm is Late Triassic, with Carnian- Norian age ammonites (Juvavites, etc.) and Halobia in marls and limestones. Babulu Fm, defined in W Timor as Late Triassic flysch facies, can be extended into E Timor to cover most rocks previously mapped as Wailuli Fm. Abundant organic matter may be source for hydrocarbons)

Davydov, V.I., D.W. Haig & E. McCartain (2013)- A latest Carboniferous warming spike recorded by a fusulinid-rich bioherm in Timor Leste: implications for East Gondwana deglaciation. Palaeogeogr. Palaeoclim. Palaeoecology 376, p. 22-38.
(online at: http://scholarworks.boisestate.edu/cgi/viewcontent.cgi?article=1150&context=geo_facpubs)
(Lensoidal limestone body of Maubisse Fm near Kulau village in central highlands of Timor Leste is bioherm with massive lower unit, including reef framework at base, and bedded grainstone upper unit. Bioherm developed on basalt substrate in warm shallow water. Fusulinid foraminifera including Schwagerina spp. and Eostaffella suggest latest Carboniferous (-earliest Permian) age. Kulau bioherm is oldest unit recognized in Maubisse Fm of Timor. Also suggest subtropical environment at paleolatitude of ~40° S, at N margin of Gondwana (where E Permian is glacial-dominated) (Authors do not consider previous interpretations that Maubisse Fm may be 'allochthonous' and not part of Australian margin; JTvG))

Davydov, V.I., D.W. Haig & E. McCartain (2014)- Latest Carboniferous (late Gzhelian) fusulinids from Timor Leste and their paleobiogeographic affinities. J. Paleontology 88, 3, p. 588-605.

(Uppermost Gzhelian (possibly lowermost Asselian) 9-24m thick bioherm on basalt near Kalau, 6 km WNW of Maubisse, in highlands of Timor Leste. With abundant foraminifera belonging to 17 genera (incl. fusulinids Ozawainellidae, Schubertellidae, Schwagerinidae, etc. Two new Schwagerina species: S. timorensis and S. maubissensis in oldest carbonate unit recorded frome Maubisse Fm. Also Eostaffella spp., Schellwienia spp. Timor was in N part of N-S East Gondwana rift system along which W margin of Australia later developed. Timor fauna most closely related to faunas from S China and Changning-Menlian region of Yunnan)

(Descriptions of basic volcanics of 'Sonnebait series' (=Maubisse complex; JTvG), associated with shallow marine Permian crinoidal limestones. Triassic-Jurassic-Cretaceous of Sonnebait series all pelagic sediments)

De Roever, W.P. (1959)- Schwach alkalischer fruhgeosynklinaler Vulkanismus in Perm der insel Timor. Geol. Rundschau 48, p. 179-184.
('Weakly alkaline, early geosynclinal volcanism in the Permian of Timor'. Permian basic volcanics of Timor (of Maubisse Terrane) mainly olivine basalts, also trachybasalt, alkali-trachyte. Do not belong in cratonic setting, but are similar to oceanic basalts and here called 'early geosynclinal')

De Smet, M.E.M, A.R. Fortuin, S.R. Troelstra, L.J. Van Marle, Mimin Karmini, S. Tjokrosapoetro & S. Hadiwisastra (1990)- Detection of collision-related vertical movements in the Outer Banda Arc (Timor, Indonesia), using micropaleontological data. J. Southeast Asian Earth Sci. 4, p. 337-356.
(Timor Central Basin fill Late Pliocene pelagic calcilutites with vitric tuffs (Batu Putih Fm), unconformably over Bobonaro scaly clay and imbricated Early Pliocene- older rocks. Batu Putih carbonates change to submarine fan clastics at ~2.2 Ma (Noele Fm). Source of turbidites was from N Timor and include serpentinite fragments. Two rel. short uplift periods: (1) >600m uplift at 2.2- 2.0 Ma, associated with creation of Central Basin and emergence of N Timor and (2) >1500m of uplift starting at 0.2 Ma and still ongoing)

De Waard, D. (1954)- Contributions to the geology of Timor. I. Geological research in Timor. Indonesian J. Natural Science (Majalah Ilmu Alam Indonesia) 110, p. 1-8.
(Summary of 1953 Timor expedition of University of Indonesia, Bandung)

De Waard, D. (1954)- Contributions to the geology of Timor, II. The orogenic main phase in Timor. Indonesian J. Natural Science (Majalah Ilmu Alam untuk Indonesia) 110, p. 9-20.
(Lalan Asu area, SW Timor, typical Palelo Series of schists overlain by Cretaceous flysch, with unconformities at base of shallow marine Eocene and Base Miocene limestones. Basal Miocene conglomerate has Miogypsinoides complanata (= Aquitanian age according to Marks 1954, but signifies zone Te4/Chattian/ latest Oligocene; JTvG). Structural analysis suggests thrusting to S and SSW. Strike directions of Cretaceous, Eocene and Miocene similar, suggesting rel. minor overthrusting in pre-Lower Miocene, main phase in Late Miocene; Sonnebait overthrusts Palelo complex)

De Waard, D. (1954)- Contributions to the geology of Timor, V. Structural development of the crystalline schists in Timor. Tectonics of the Lalan Asu Massif. Indonesian J. Natural Science (Majalah Ilmu Alam untuk Indonesia) 110, 4-6, p. 143-153.
(Structural analysis of foliation in Lalan Asu schists suggests 2 main structural events; (1)'Pre-Permian?' event caused E-W striking foliation and low-medium grade metamorphism and (2) Late Miocene folding/thrusting,

with minor tectonic events in-between. Serpentine masses, occasionally with gabbro, along border of massif between schist and overthrust series)

De Waard, D. (1954)- Contributions to the geology of Timor, VI. The second geological Timor expedition, preliminary results. Indonesian J. Natural Science (Majalah Ilmu Alam untuk Indonesia) 110, 4-6, p. 154-160.
(Tectonics of Timor very complex; overthrusting present, but not like rel. coherent and flat alpine nappes. Crystalline massifs and associated ophiolites probably lenticular masses in overthrust succession. Chaotic structures in Sonnebait series suggest gravity tectonics)

De Waard, D. (1955)- Contributions to the geology of Timor, VII. On the tectonics of the Ofu series. Indonesian J. Natural Science (Majalah Ilmu Alam untuk Indonesia) 111, 4-6, p. 137-143.
(Ofu series in mountainous area near S coast of W Timor (later called Kolbano foldbelt = young accretionary prism of distal Australian NW margin rocks; JTvG) consists of Jurassic-Cretaceous marly limestones, highly folded with E-W orientation of fold-axes and dominantly N-ward dips. Ofu series may be thrust over more marly Permo-Triassic 'parautochthonous' Kekneno series)

De Waard, D. (1955)- Contributions to the geology of Timor, VIII. Tectonics of the Sonnebait overthrust unit near Nikiniki and Basleo. Indonesian J. Natural Science (Majalah Ilmu Alam untuk Indonesia) 111, 4-6, p. 144-150.
(SW Timor Sonnebait overthrust unit in Nikiniki- Basleo region with famous Permian-Triassic fossil localities. Mainly composed of 500-750m of Permian shales and reddish limestones with common pillow basalt flows, subordinate Triassic cephalopod limestones and U Cretaceous deep-sea clays with manganese nodules. Structurally not as complex as previously reported: NW-SE trending open folds with wavelength of 1.5- 2 km. Tectonically thrusted over Ofu series in S, which is separate overthrust sheet with different stratigraphy (Jurassic-Cretaceous deep-water marly limestones) and with E-W trending fold axes. Different orientations suggest two separate fold-thrust events))

De Waard, D. (1956)- Contributions to the geology of Timor, IX. Geology of a N-S across Western Timor. Indonesian J. Natural Science (Majalah Ilmu Alam untuk Indonesia) 112, 2, p. 1-13.
(W Indonesian Timor northern and southern zones of overthrust structures, separated by central basin with latest Miocene-Pleistocene sediments and bordered on S by major (~2000m of throw) Nikiniki fault. Overthrusting completed in Early Miocene. Orogenic movements continued with faulting, tilting of blocks, and formation of central depression. Position of Tertiary volcanic rocks along N coast not yet clear)

De Waard, D. (1957)- Contributions of the geology of Timor, XII. The third Timor geological expedition, preliminary results. Indonesian J. Natural Science (Majalah Ilmu Alam untuk Indonesia) 113, p. 7-43.
(1957 Timor Expedition. Name Mutis unit proposed for tectonic unit composed of crystalline basement overlain by Palelo (+U Jurassic?+ Cretaceous greywackes and volcanics), Eocene limestone and volcanics and Lower Miocene reefal limestones and volcanics, all folded (=Banda Terrane of Harris). Fatus, previously assumed to be separate tectonic units, now considered to be bioherms in Permian, Triassic and Jurassic of Sonnebait overthrust unit. Only one overthrust sheet of importance: Sonnebait overthrust, which overlies all other tectonic units, incl. Mutis and parautochthonous Kekneno unit)

De Waard, D. (1957)- Zones of regional metamorphism in the Lalan Asu Massif, Timor. Proc. Kon. Nederl. Akademie Wetenschappen, Amsterdam, 60, p. 383-392.
(Five metamorphic zones ranging from muscovite-chlorite subfacies to amphibolite facies in crystalline schists of Lalan Asu massif, W Timor. Massif surrounded by marly sediments of Sonnebait overthrust sheet)

De Waard, D. (1959)- Anorthite content of plagioclase in basic and pelitic crystalline schists as related to metamorphic zoning in the Usu massif. Timor. American J. Science 257, p. 553-562.
(Sampling of schists in Usu massif yielded detailed pattern of isopleths based on An values of plagioclase. An10 isopleth marks isograd separating greenschist facies from almandine amphibolite facies. Grade of metamorphism probably responsible for plagioclase equilibrium values)

Dias, R. (2012)- Strike-slip tectonics in arc-continent collision: The Timor-Leste example. First Int. Geological Congress of Geology of Timor-Leste, Dili 2012, p. 53-58. *(Extended Abstract)*

(Manganese nodules from Cretaceous red clay from Noil Tobe, W Timor, chemically very similar to Pacific-Indian oceanic deep sea nodules, providing strong confirmation of deep sea origin)

Ely, K.S. (2009)- Geochronology of Timor-Leste and seismo-tectonics of the southern Banda Arc. Ph.D. Thesis, University of Melbourne, p. 1-262.
(online at: https://minerva-access.unimelb.edu.au/handle/11343/35296)
(Detrital zircons from N Timor Leste Aileu Metamorphic Complex of N Timor Leste show age modes at 270-425 Ma, 860-1180 Ma and 1460-1870 Ma, favoring sediment source from E Malaya- Indochina and maximum depositional age of 270 Ma (E-M Permian). Aileu Complex cooling ages of 6-10 Ma, implying metamorphism started by at least ~12 Ma. Metamorphism attributed to arc setting rather than collision of Australian continent with Banda Arc. Atauro island N of Timor bi-modal subaqueous volcanism ceased by ~3 Ma, followed by uplift of coral reef terraces to 700m around island. N of Timor absence of intermediate depth seismicity attributed to slab window down to 350 km depth. Slab under W Savu Sea in down-dip compression at ~70-g 300 km, beneath region of arc with closest spacing of volcanoes in Sunda-Banda arc system. Unusual state of stress attributed to subduction of N extension of Scott Plateau)

Ely, K.S., M. Sandiford, D. Phillips & S.D. Boger (2014)- Detrital zircon U-Pb and 40Ar/39Ar hornblende ages from the Aileu Complex, Timor-Leste: provenance and metamorphic cooling history. J. Geol. Soc., London, 171, p. 299-309.
(online at: http://citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.875.2812&rep=rep1&type=pdf)
(Detrital zircons from metasediments of Permian Aileu Complex of N Timor Leste have major U-Pb age modes at 275-440 Ma (peak at 290 Ma, reflecting nearby E Permian magmatism?), 860-1240 Ma and 1460-1870 Ma, most compatible with sediment source from now fragmented Sula Spur. 40Ar/39Ar cooling ages of hornblende show W parts cooling through hornblende closure temperature by 10 Ma and central parts by 6 Ma, consistent with variable exhumation history. Onset of cooling by 10 Ma implies metamorphism was probably coeval with initiation of Banda Arc. Aileu Complex cooling ages record deformation related to fragmentation of Sula Spur and early development of Banda Arc, rather than collision between Australian continent and Banda Arc)

(online at: www.dwc.knaw.nl/DL/publications/PU00016371.pdf)
('On the systematics of the aulacocerates'. Study of >3000 specimens of ribbed belemnite Aulacoceras from Triassic of W Timor (probably Late Triassic 'Halstatter facies'-equivalent), collected by Jonker Timor expedition. Timorese aulacocerates, originally described as Asteroconites savuticus (Boehm) 1907 and Aulacoceras timorense Wanner 1911, may be varieties of alpine species Aulacoceras sulcatum Von Hauer)

Gheyselinck, R.F.C.R. (1937)- Permian trilobites from Timor and Sicily. Doct. Thesis University of Amsterdam, Scheltema & Holkema, Amsterdam, p. 1-108. *(Unpublished)*
(Comprehensive study of (generally rare) trilobites from Permian of Timor. About 100 specimens, 7 species, mainly from Basleo. Most common species is Neoproetus indicus Tesch. No locality maps or stratigraphic info)

Giani, L. (1971)- The geology of the Belu District of Indonesian Timor. Masters Thesis, Imperial College, University of London, p. 1-122.
(online at: https://spiral.imperial.ac.uk/handle/10044/1/35410)
(Reconnaissance study of easternmost district of Indonesian Timor. Stratigraphy-structure similar to adjacent TimorLeste: (1) highly deformed Autochthonous units (Permian Cribas Fm turbidites with plant material, Triassic Aitutu Fm radiolarian calcilutite with Halobia and thin bituminous shales (no benthic fauna) and younger? Babulu Mb siliciclastic flysch; possible Jurassic Wai Luli Fm); (2) three overthrust allochthonous units (klippen of Maubisse Fm Permian crinoid limestones with thin chert layers and olivine pillow basalts, Aileu Fm metamorphosed Permian, Lolotoi quartz-mica schists). Emplacement of overthrust sheets during Ramelauean orogeny, dated as M Miocene in E Timor. Lolotoi Complex was emplaced before arrival of Maubisse Fm?. (3) Fatu Mondeo is E Miocene Cablac Limestone (Miogypsina, Spiroclypeus); (4) All deformed autochthonous and overthrust units overlain unconformably by Bobonaro olistostrome of exotic blocks in scaly (slickenside) clay matrix with Permian-Pliocene? foraminifera; (5) Olistostrome overlain by little deformed Late Miocene- Quaternary Viqueque Fm; (6) Quaternary coral reef terraces uplifted to 300m. With mud volcanoes, Oetfo gas seep and small Roti Mutin oil seep.)

Glasby, G.P. (1978)- Deep-sea manganese nodules in the stratigraphic record: evidence from DSDP cores. Marine Geol. 28, p. 51-64.
(Core records of first 370 holes of DSDP Project shows manganese nodules relatively uncommon in stratigraphic column and >42% of nodules are from Pleistocene. Onset of high ocean bottom current velocities at ~3.5 Ma may have favored nodule growth through much of Pacific Ocean. Manganese nodules from pelagic red clay on Timor formed in Cretaceous when Antarctic circumpolar current was deflected N of Australia)

Glenister, B.F. & W.M. Furnish (1987)- New Permian representatives of ammonoid superfamilies Marathonitaceae and Cyclolobaceae. J. Paleontology 61, 5, p. 982-998.
(New species Eohyattoceras gerthi and Cardiella martodjojoi from late Early Permian (Roadian) of Basleo and Bitauni, Timor. Demarezites oyensi (Gerth, 1950 from Tae Wei, Basleo) and D. lidacensis (de Roever, 1940, from Lidak district), formerly assigned to Waagenoceras, ancestral to Waagenoceras-Cyclolobus lineage, redescribed from Roadian of Timor)

Glenister, B.F. & W.M. Furnish (1988)- Patterns in stratigraphic distribution of Popanocerataceae, Permian Ammonoids. Senckenbergiana Lethaea 69, 1-2, p. 43-71.
(With descriptions of Propopanoceras boesei (Smith) from Somohole and Epitauroceras soewarnoi n.sp. from Amarassian beds at Kuafeu, Baun area, Timor)

Glenister, B.F., W.M. Furnish & Z. Zhou (2004)- *Paedopronorites*, a new Upper Permian (Wuchiapingian) ammonoid from Indonesia (Timor). J. Paleontology 78, 5, p. 1014-1015.
(New Permian ammonoid from Amarassi Beds, Kuafeu (Koeafeoe), Baun area, Amarassi Province, W Timor. Associated with cyclolobid genera Timorites and Cyclolobus. No strat info)

Glenister, B.F., D.L. Windle & W.M. Furnish (1973)- Australasian Metalegoceratidae (Lower Permian Ammonoids). J. Paleontology 47, 6, p. 1031-1043.
(Taxonomy of Lower Permian Juresanites- Metalegoceras- Pseudoschistoceras ammonoid lineage, based on collections from W Australia, Timor and Oman. Names Paralegoceras sundaicum form. evoluta and form. involuta replaced by genera Metalegoceras and Pseudoschistoceras. Descriptions of Sakmarian Juresanites somoholense (Haniel) and J. hanieli (Smith) (both formerly Gastrioceras). Australian species M. clarkei Miller conspecific with senior Indonesian synonym, M. australe (Smith). Metalegoceratidae are distinctive element of Lower Permian 'Boreal' ammonoid realm)

Grady, A.E. (1975)- A reinvestigation of thrusting in Portuguese Timor. J. Geol. Soc. Australia 22, p. 223-228.
(Field relations from Maubisse region of Portuguese Timor fail to support hypothesis of S-ward overthrusting of Permian rocks or postulate that Maubisse Fm represents a mid-Tethys island group (This 'autochthonous' model has been widely criticized in other papers; JTvG))

Grady, A.E. & R.F. Berry (1977)- Some Palaeozoic-Mesozoic stratigraphic-structural relationships in East Timor and their significance in the tectonics of Timor. J. Geol. Soc. Australia 24, p. 203-214.
('Autochthonous' model suggested for development of Timor, with essentially no allochthonous pre-Cenozoic material)

Grady, A.E. & R.F. Berry (1980)- The significance of blue amphibole in Timor. Inst Australasian Geodynamics (Flinders University) Publ. 80, 5, p.

Gurich, G. (1893)- Uber ein Vorkommen von Lias und oberem Jura auf der Insel Rotti bei Timor in Ostindien und.... 70th Jahresbericht Schlesise Gesellschaft vaterlandische Kultur, II, Naturw. Abt., Breslau, p. 16-18.
('On an occurrence of Lias and Upper Jurassic on the island Roti near Timor in the East Indies..'. First? (brief) report of Jurassic fossils in Indonesia, from Roti Island near Timor: Lower Jurassic ammonites (Arieticeras, Lytoceras) and Upper Jurassic belemnites (Belemnites gerardi group). Collected by German Dr. Schneider from Surabaya and sent to Ferd. Roehmer in Germany. No figures (see also Rothpletz 1892))

Hadimuljono, J.S., D. Yensusminar, A.B. Wicaksono & S. Suliantara (2016)- Rembesan migas di daerah Timor Barat. Lembaran Publikasi Minyak dan Gas Bumi (Lemigas) 50, 3, p.

(?online at: http://www.journal.lemigas.esdm.go.id/ojs/index.php/LPMGB/article/view/2/1)
('The oil and gas seepages in West Timor'. Many oil and gas seeps in W Timor, generally associated with mud volcanoes. Gas seeps in all mud volcanoes in W Timor; oil seeps only at mud volcanoes in S part of W Timor. Gas mainly methane (CH4) and minor ethane (C2H6) with high N2 content. Gas chromatography of oil seeps suggest oil probably originated from lacustrine or marine-transition environments)

Hadiwisastra, S. (1987)- Plio-Plistocen nannofosil biostratigrafi dari daerah Soe, Timor. Proc. 15th Ann. Conv. Indon. Assoc. Geol. (IAGI), Yogyakarta 1986, 14p.
('Plio-Pleistocene nannofossil biostratigraphy of the Soe area, Timor')

Haig, D.W. (2004)- Stratigraphic reconstruction of Timor Leste and correlation to the Bonaparte Basin. PESA Newsletter 73, p. *(Geology in Timor Symposium Abstract)*
(Wai Luli Formation type area clastics ranges in age from Late Permian- M Jurassic. Stratigraphic succession similar to Bonaparte Basin)

Haig, D.W. (2012)- Palaeobathymetric gradients across Timor during 5.7-3.3 Ma (latest Miocene-Pliocene) and implications for collision uplift. Palaeogeogr. Palaeoclim. Palaeoecology 331-332, p. 50-59.
(Paleobathymetry analysis of oldest post-collision deposits in Timor, from distributions of planktonic and benthic foraminifera in chalk, marl and mudstone successions that accumulated during 5.7-3.3 Ma. Paleo water depths between 500-2500m, deepening from N to S, E and W)

Haig, D.W. (2018)- Key stratigraphic horizons for assembling a revised tectonostratigraphic framework for Timor-Leste. In: Proc. 4th IPG Int. Geosciences Conference on Timor-Leste, Dili 2018, p. 19-27.
(online at: http://ipg.tl/wp-content/uploads/2018/10/PROCEEDING-4th-Int.-Conference-2018.pdf)
(Major rock associations on Timor: (1) Synorogenic (latest Miocene- Holocene, between Australian continent and volcanic Banda Arc, accumulated as present-day island of Timor formed; (2) Timor- Scott Plateau (Late Jurassic- early Late Miocene); (3) East Gondwana Interior Rift (Late Carboniferous/Cribas- M Jurassic/ Wailuli; represent deposits of pre-collision Late Miocene Australian continental margin); (4) Overthrust Terrane (includes Gondwanan/island arc/ocean crustal fragments, emplaced in Late Miocene over NW Australian continental margin during collision)

Haig, D.W. & A.N. Bandini (2013)- Middle Jurassic radiolaria from a siliceous argillite block in a structural melange zone near Viqueque, Timor Leste: paleogeographic implications. J. Asian Earth Sci. 75, p. 71-81.
(Large thin-bedded siliceous argillite block in Bobonaro melange at Viqueque, S Timor Leste, associated with blocks of pillow basalts, near contact with post-orogenic Viqueque basin deposits. Contains M Jurassic (late Bathonian- E Callovian) radiolarian assemblage of 55 species. Fauna little similarity to other Jurassic radiolarian assemblages known from Timor or from Roti, Sumatra, S Kalimantan and Sula. Interpreted as part of Noni Gp, originally described as lower part of Palelo Series in W Timor. Age close to that of continental breakup in area, suggesting deposition in newly rifted Indian Ocean (new 'Indian Ocean Megasequence'))

Haig, D.W. & E. McCartain (2007)- Carbonate pelagites in the post-Gondwana succession (Cretaceous-Neogene) of East Timor. Australian J. Earth Sci. 54, 6, p. 875-897.
(Upper parts of Permian- M Jurassic 'Gondwana Megasequence' structurally juxtaposed against Aptian- Late Miocene carbonate pelagites. Pelagites probably several 100m thick, bathyal, deposited unconformably above Gondwana succession after continental breakup. Cementation, stylolitisation and vein formation after early Late Miocene (after 10.9- 9.8 Ma). Deformed succession overlain by relatively undeformed Plio- Pleistocene Viqueque Megasequence (N18-N23). First distal turbidites were from 4.2-3.35 Ma; proximal turbidite deposition from ~3.35 Ma, with clasts from emerging Timor island to N. M bathyal continental terrace setting continued from Cretaceous- Paleogene to E Pliocene. Soft-sediment mixing in deformed pelagites and Bobonaro Melange under Viqueque Gp suggests Late Miocene (9.8-5.6 Ma) tectonic mobilisation of sedimentary units, with mud volcanoes erupting on seafloor)

Haig, D.W. & E. McCartain (2010)- Triassic organic-cemented siliceous agglutinated foraminifera from Timor-Leste: conservative development in shallow marine environments. J. Foraminiferal Research 40, 4, p. 366-392.

(49 species of agglutinated foraminifera in 11 facies associations in Triassic basinal deposits of Timor Leste. One genus and five species new. Fauna cosmopolitan composition. Coherent stratigraphic sections not preserved and stratigraphic reconstruction is based on correlations using conodonts, palynomorphs and other forams. Most samples Upper Triassic, some Lower Triassic. Facies associations range from those influenced by sediment from nearby carbonate banks to prodelta and delta-front associations)

Haig, D.W. & E. McCartain (2012)- Intraspecific variation in Triassic ophthalmidiid Foraminifera from Timor. Revue Micropaleontologie 55, 2, p. 39-52.
(Four ophthalmidiid species from Triassic mudstones and wackestones. In Timor Leste, A. bandeiraensis, K. atsabensis and S. grunaui found with Carnian conodonts, at another locality K. atsabensis occurs with conodonts suggestive of M Triassic)

Haig, D.W., E. McCartain, L. Barber & J. Backhouse (2007)- Triassic- Lower Jurassic foraminiferal indices for Bahaman-type carbonate-bank limestones, Cablac Mountain, East Timor. J. Foraminiferal Research 37, 3, p. 248-264.
(Peloidal- oolitic limestones on Cablac Mountain in E Timor contain Triassic or Lower Jurassic small foraminifera, not Lower Miocene as previously mapped. E Jurassic (Sinemurian-Pliensbachian) age indicated by Meandrovoluta asiagoensis, Everticyclammina praevirguliana and palynomorphs. Other limestones Late Triassic- Early Jurassic, based on Duotaxis metula. Basinal facies of nearby Wai Luli Valley indicate Late Triassic (Carnian) transported carbonate-bank foraminiferal assemblage. This suggests carbonate banks developed locally on topographic highs in seas that flooded interior-rift basins in this part of Gondwana and complex facies array of deep-water muds, deltaic sands, and carbonate shoals)

Haig, D.W., E.W. McCartain, M. Keep & L. Barber (2008)- Re-evaluation of the Cablac Limestone at its type area, East Timor: revision of the Miocene stratigraphy of Timor. J. Asian Earth Sci. 33, p. 366-378.
(Cablac Limestone supposedly a Lower Miocene shallow marine carbonate, but is of Late Triassic- E Jurassic age at Cablac Mountain type locality. Crush breccia at N flank Cablac Mountain formerly regarded as basal conglomerate of Cablac Lst reinterpreted as breccia along high angle fault between 'Asian' Banda Terrane and overthrust limestone)

Haig, D.W., E. McCartain, A.J. Mory, G. Borges, V.I. Davydov, M. Dixon, A. Ernst, S. Groflin, E. Hakansson, M. Keep, Z. Dos Santos, G.R. Shi & J. Soares (2014)- Postglacial Early Permian (late Sakmarian-early Artinskian) shallow-marine carbonate deposition along a 2000 km transect from Timor to West Australia. Palaeogeogr. Palaeoclim. Palaeoecology 409, p. 180-204.
(Late Sakmarian- E Artinskian carbonate deposition widespread in marine intracratonic rift basins from Timor to N Perth Basin, spanning ~20° of paleolatitude (35-55°S). Type section of Maubisse Lst in Timor-Leste compared to sections in Canning Basin, S Carnarvon Basin (Callytharra Fm) and N Perth Basin (Fossil Cliff Mb). Carbonate units have no glacial influence, overlie glacially influenced strata in S. Limestone deposition under very shallow marine conditions, and similar grain composition, dominated by bryozoan and crinoidal debris. Tubiphytes, gastropod and bivalve shell debris, echinoid spines, solitary rugose corals and trilobite elements rare. Lack of tropical elements such as fusulinid foraminifera, colonial corals or dasycladacean algae indicate temperate marine conditions with only small increase in temperature to N. Carbonate deposits represents warmer phase than preceding glacially influenced Asselian- E Sakmarian interval and subsequent cool phase of 'mid' Artinskian that is followed by significant warming during late Artinskian- E Kungurian)

Haig, D.W., A.J. Mory, E. McCartain, J. Backhouse, E. Hakansson, A. Ernst, R.S. Nicoll, G.R. Shi, J.C. Bevan, V.I. Davydov, A.W. Hunter, M. Keep et al. (2017)- Late Artinskian- Early Kungurian (Early Permian) warming and maximum marine flooding in the East Gondwana interior rift, Timor and Western Australia, and comparisons across East Gondwana. Palaeogeogr. Palaeoclim. Palaeoecology 468, p. 88-121.
(U Artinskian- Kungurian deposits in Timor-Leste and Canning, S Carnarvon and N Perth basins of W Australia formed between 35- 55°S paleolatitude in East Gondwana interior rift, a precursor to rift that 100 My later formed Indian Ocean in region. Timor lay near main axis of E Gondwana rift. Main depocentres developed by faulting initiated in latest Carboniferous. Cool conditions in early Late Artinskian (water T 0-4 °C), followed by rapid warming in late Artinskian and maximum marine flooding near Artinskian-Kungurian

boundary. Carbonate mounds,with larger fusulines and algae developed in N part of rift; Tubiphytes, conodonts, and brachiopods with Tethyan affinities to migrate into marginal-rift basins. Bua-bai Lst (= 'upper Maubisse Gp) locally rich in Late Artinskian? fusulinid Praeskinnerella. Similar pattern of climate change in Carboniferous- E Permian between E Gondwana rift and Lhasa and Sibumasu terranes)

Haig, D.W., Z.K. Mossadegh, J.H. Parker & M. Keep (2019)- Middle Eocene neritic limestone in the type locality of the volcanic Barique Formation, Timor-Leste: microfacies, age and tectonostratigraphic affinities. J. Asian Earth Sci. X, 1, 20p.
(online at: https://www.sciencedirect.com/science/article/pii/S2590056018300033)
(Occurrences of Eocene Alveolina-Nummulites- Discocyclina limestones in mainly volcanic Barique Fm. Ages of limestone using planktonic and benthic foraminifers late M Eocene (~37.8-43.6 Ma). Similar Eocene limestone-volcanic association widespread in Timor, but not known along NW Shelf of Australia. Usually found in coherent areas of outcrop with Late Mesozoic Palelo Group, oceanic facies (radiolarites to carbonate pelagites), E Jurassic carbonate-bank deposits, etc.. This is Overthrust Terrane Association. Cretaceous- E Miocene units of Overthrust Terrane Association (incl. Barique Group) similar to coeval units in Sumba and considered fragments of fore-arc of Banda Arc ('Banda Terrane'))

Haile, N.S., A.J. Barber & D.J. Carter (1979)- Mesozoic cherts on crystalline schists in Sulawesi and Timor. J. Geol. Soc. London 136, p. 65-70.
(online at: http://citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.820.2026&rep=rep1&type=pdf)
(Chert-bearing deep water Jurassic-Cretaceous, unconformable on metamorphics of continental origin in SW Sulawesi and Timor, suggesting Sulawesi and Timor probably part of continuous terrain during deposition of radiolarian cherts. Description of Noil Toko section of Miomaffo complex where Late Jurassic- E Cretaceous radiolarian cherts overlie Mutis-Miomaffo metamorphics)

Hamlet, B. (1928)- Permische Brachiopoden, Lamellibranchiaten und Gastropoden von Timor. In: H.A. Brouwer (ed.) 2e Nederlandsche Timor-Expeditie VI, Jaarboek Mijnwezen Nederlandsch-Indie 56 (1927), Verhandelingen 2, p. 1-115.
(Permian brachiopods and molluscs from W Timor, collected by 1911 Molengraaff and 1915-1917 Jonker expeditions. Incl. Leptodus from Fatu Kuat. Little or no stratigraphy or locality information)

Haniel, C.A. (1915)- Ammoniten aus dem Perm der Insel Letti. Jaarboek Mijnwezen Nederlandsch Oost-Indie 43 (1914) Verhandelingen 1, p. 161-165.
('Ammonites from the Permian of Leti Island' (E of Timor). Brief descriptions of presumably Early Permian ammonites Paralegocereas sundaicum (= Metalegoceras), Agathiceras sundaicum n.sp. and Propinacoceras sp. from greywacke shale at S slope of 'small Woerlawan' Mountain, Leti. Similar to Bitauni fauna from W Timor)

Haniel, C.A. (1915)- Die Cephalopoden der Dyas von Timor. In: J. Wanner (ed.) Palaontologie von Timor, Schweizerbart, Stuttgart, 3, 6, Schweizerbart, Stuttgart, p. 1-153.
('The cephalopods from the Dyas (= Permian) of Timor'. First and only monograph on Permian ammonites from 35 localities on W and E Timor, expanding on brief earlier papers by Beyrich (1865), Rothpletz (1892) and Boehm (1907). Incl. species of Agathiceras, Cyclolobus, Popanoceras, Paralegoceras, etc. New genera Timorites and Sundaites. New species incl. Sundaites levis. Also straight nautiloids Orthoceras spp.)

Harahap, B.H. (2003)- Melange and broken formation on the road from Baucau to Manatuto, Timor Leste. Buletin Geologi (ITB) 35, 1, p. 25-42.
(Melange and broken formation along Baucau- Manatuto road. Melange with scaly mudstone matrix and clasts of crinoidal limestone, pelagic limestone, oolitic limestone, radiolarian chert, sandstone, serpentinite, pillow lava and volcanic rock, fragments of manganese. Broken formation composed mainly of Triassic Aitutu Fm and Permian Maubisse and Atahoc Fms. Most clasts, except serpentinite and radiolarian chert same as broken formation units (also occur as more coherent, mappable units in Central Range of Timor Leste). Serpentinite, radiolarian chert and possibly some pillow lavas thought to be derived from Flores Sea Basin to N. Melange and broken formation may have formed during Australian continent- Banda Arc collision in Pliocene)

Harjanto, A. & C. Danisworo (2013)- Karakteristik mangan (Mn) di daerah Sipul dan sekitarnya, Kecamatan Niki-Niki, Kabupaten Soe, Propinsi Nusa Tenggara Timur. J. Ilmiah Magister Teknik Geologi (UPN) 6, 1, 14p.
(online at: http://jurnal.upnyk.ac.id/index.php/mtg/article/view/250/212)
'(Characteristics of manganese (Mn) in Sipul and surrounding area, Niki-Niki, District Soe, West Timor'. Manganese in Late Cretaceous- Eocene Ofu Fm pelagic sediments N of Sipul. Mineralization of pyrolusite and psilomelane as 2-15 cm thin layers in calcilutite and chert series, with Mn content up to 52%. Manganese deposition probably related to hydrothermal processes)

Harloff, C.E.A. (1936)- Vondst van een Radiumhoudend uraniumerts in de Timorcollectie van den Dienst van den Mijnbouw. De Ingenieur in Nederlandsch-Indie (IV) 3, 4, p. 64-70.

(On the Australian continental margin- Banda arc collision zone, mainly around Timor- Savu- Sumba. Collision began in C Timor at end of Miocene)

Harris, R. (2006)- Rise and fall of the Eastern Great Indonesian Arc recorded by the assembly, dispersion and accretion of the Banda Terrane, Timor. Gondwana Research 10, 3-4, p. 207-231.
(online at: http://geology.byu.edu/Home/sites/default/files/2006-banda-terrane-gr.pdf)
(Banda Terrane is remnant of Jurassic-Eocene arc-trench system that formed E part of Great Indonesian Arc. Arc rifted apart during Eocene- Miocene supra-subduction zone spreading, which dispersed ridges of Banda Terrane embedded in young oceanic crust as far S as Sumba and Timor. In Timor Banda Terrane high-level thrust sheets, detached from Banda Sea upper plate and uplifted by collision with NW Australia margin. Thrust sheets contain medium grade metamorphics overlain by Cretaceous- Miocene forearc deposits. Igneous zircons <162 Ma with clusters of ages at 83 Ma and 35 Ma. Ar/Ar plateau ages from metamorphics cluster at 32-38 Ma. Cooling curves show exhumation from ~550 °C to surface between 36-28 Ma; after this time no evidence of metamorphism. Banda Terrane rocks and events similar to E edge of Sunda Shelf and Banda Sea floor)

Harris, R. (2011)- The nature of the Banda Arc-continent collision in the Timor region. In: D. Brown & P.D. Ryan (eds.) Arc-continent collision, Frontiers in Earth Sciences 2, Springer Verlag, Heidelberg, p. 163-211.

Harris, R. (2012)- Free at last: new data helps Timor Leste redefine the processes of arc-continent collision. First Int. Geological Congress of Geology of Timor-Leste, Dili 2012, Abstract Book, p. 63-66.
(Extended Abstract)

Harris, R.A. & M.G. Audley-Charles (1987)- Taiwan and Timor neotectonics: a comparative review. Mem. Geol. Soc. China 9, p. 45-61.
(Taiwan and Timor both thrust belts formed by Pliocene- Recent convergence between passive continental margin and volcanic arc. Taiwan greater rate of uplift, thicker deforming sedimentary wedge and well-defined seismically active suture zone)

Harris, R.A., J.S. Kaiser, A.J. Hurford & A. Carter (2000)- Thermal history of Australian passive margin cover sequences accreted to Timor during Late Neogene arc-continent collision, Indonesia. J. Asian Earth Sci. 18, 1, p. 47-69.
(online at: http://geology.byu.edu/home/sites/default/files/2000-thermal-history-harris-et-al.pdf)
(Paleotemperature and apatite fission track analysis of Australian continental margin cover sequences accreted to active Banda arc-continent collision indicate little to no heating during late Neogene uplift and exhumation. Thrust stacking of rise, slope and shelf units produces inverted vertical profile of increasing apatite fission track age with depth. Lack of any long confined track lengths in apatite from all units requires rapid and recent exhumation of thrust stack, coincident with rapid phases of Plio-Pleistocene exhumation These data preclude pre-Late Miocene tectonic burial or pre-Pliocene exhumation of NW Australian continental margin)

Harris, R.A. & T. Long (2000)- The Timor ophiolite, Indonesia: model or myth? Geol. Soc. America (GSA), Spec. Paper 349, p. 321-330.
(Only parts of ophiolite sequence of Timor are small bodies of spinel lherzolite and volcanic rocks. Lherzolite mostly as blocks in Bobonaro melange, and similar to peridotites from abyssal and passive-margin settings. E Timor lherzolite associated with Aileu metamorphic complex, with Mesozoic prograde metamorphism increasing toward lherzolite bodies via Barrovian zonation. Aileu complex and lherzolites similarly affected by Late Neogene collisional (retrograde) metamorphism. W Timor Atapupu and Nefomasi lherzolites indistinguishable from those of E Timor. Position of lherzolite indicates affinity to thrust sheets accreted from distal edge of Australian continental margin (lower plate) rather than forearc basement. Lherzolite and volcanics in Ocussi region different and may represent parts of young, SSZ ophiolite, emplaced less than few Myr of birth).

Harris, R.A., R.K. Sawyer & M.G. Audley-Charles (1998)- Collisional melange development: geologic associations of active melange-forming processes with melange facies in the western Banda orogen, Indonesia. Tectonics 17, 3, p. 458-479.
(online at: http://onlinelibrary.wiley.com/doi/10.1029/97TC03083/pdf)
(Bobonaro melange facies include (1) broken formation, (2) matrix-rich mud injections, (3) mixed block-in-clay facies. Most important control is whether formed beneath or in front of upper plate Banda forearc Terrane. Kolbano Mts (Pliocene fold- thrust wedge of S Timor, structurally contiguous with Timor Trough deformation front) melange mostly broken formation and matrix-rich injections of mud from Jurassic- Cretaceous. Mud diapirs rise from near decollement along fault conduits. Melange in hinterland of orogenic wedge dominantly block-in-clay facies with large blocks from roof thrust sheets of Banda Terrane and Maubisse Fm units. At base of thrust sheets is Sonnebait Disruption Zone (SDZ), the initial suture between Banda Terrane and Australian margin sequences in Late Miocene- E Pliocene. Thickest accumulations of block-in-clay melange at S edge of SDZ, near Central/ Viqueque basins. Extent of block dispersion and mixing in SDZ indicative of intense shear strains perhaps induced by oversupply of accretable material when suture zone clogged by underthrusting of Australian continental margin)

Harris, R.A., M.W. Vorkink, C. Prasetyadi, E. Zobell, N. Roosmawati & M. Apthorpe (2009)- Transition from subduction to arc-continent collision: geological and neotectonic evolution of Savu, Indonesia. Geosphere 5, p. 152-171.
('Savu melange' product of Sunda/Banda arc- Australian continent collision. Blocks of Permian- Paleogene indurated sandstone, limestone and metamorphic and igneous rocks floating in muddy matrix, correlated with

Bobonaro melange of Timor and associated with recent mud diapyrism. Previously unrecognized units of pillow basalt interlayered with Jurassic beds. Savu 1 well TD at 1227m in Cretaceous clastics (=different from Scott Plateau, but similar to Sumba). Includes detailed geological map and cross sections of S-C Savu. Island emergence documented by uplifted coral terraces encrusting highest ridges to 338m elevation: U/Th ages of uplifted coral yields ages of 122 ka, indicating slow uplift rates of 0.2 mm/yr)

('Contributions to the petrography of West Timor'. Petrographic descriptions of rocks collected by Wanner (1909, 1911) in W Timor. Igneous (diorite, gabbro, peridotite, lherzolite, serpentinite), volcanics (quartz keratophyr, andesite, diabase) and metamorphics (amphibolites, chlorite schist, mica schist and epidote schist). No figures)

Ishikawa, A., Y. Kaneko, A. Kadarusman & T. Ohta (2007)- Multiple generations of fore-arc mafic-ultramafic rocks in the Timor- Tanimbar ophiolite, Eastern Indonesia. In: M. Santosh & S. Maruyama (eds.) Island arcs past and present, Gondwana Research 11, p. 200-217.
(Mafic-ultramafic rocks in Timor-Tanimbar region suggest uplift of fragments of mantle-crust by buoyant subduction of Australian continent. Peridotite masses in Timor (Mutis, Atapupu, Dili) mostly fertile (lherzolitic) in compositions. Overlying Ocussi volcanics resemble island-arc tholeiite, inconsistent with genetic relationship with Timor lherzolites. In eastern islands (Moa, Dai) ophiolitic rocks island-arc affinities. Petrological and geochemical variations best explained by combination of (1) temporal change of igneous activity possibly associated with development of forearc basin and (2) emplacement of spatially different forearc regions in each locality. Fertile lherzolite in forearc setting, high-Mg andesite magmatism, inverted metamorphic grade in associated metamorphics and formation of marginal basins may be linked to injection of high-T asthenospheric materials into mantle wedge)

Ishikawa, A., Y. Kaneko, T. Ohta & Y. Isozaki (2011)- Ophiolites in the non-volcanic Banda outer arc of East Indonesia. Journal of Geography (Chigaku Zasshi) 120, 1, p. 52-64.
(In Japanese; online at: www.jstage.jst.go.jp/article/jgeography/120/1/52/_pdf)

Jafar, S.A. (1975)- Calcareous nannoplankton from the Miocene of Rotti, Indonesia. Verhandelingen Kon. Nederl. Akademie Wetenschappen, Afd. Natuurkunde, Amsterdam, ser. 1, 28, p. 1-99.
(online at: www.dwc.knaw.nl/DL/publications/PU00010962.pdf)
(Calcareous nannoplankton from single chalk sample 168 from Bebalain, Roti, collected by Molengraaff 1910 and previously studied by Tan Sin Hok (1927) and Kamptner (1955). Seventy-four recognizable autochthonous species of calcareous nannoplankton belonging to 18 genera. Age of sample upper NN9, Discoaster hamatus zone (= early Late Miocene; ~10 Ma). Also common reworked E Cretaceous- E Miocene nannoplankton)

Jafar, S.A. (1975)- Some comments on the calcareous nannoplankton genus *Scyphosphaera* and the neotypes of *Scyphosphaera* from Rotti, Indonesia. Senckenbergiana Lethaea 56, p. 365-379.

Jansen, H. (1934)- Die Variationsstatistische Methode angewandt auf ein groszes Material von *Schizoblastus* aus dem Perm von Timor und einige neue Anomalien dieser Gattung. Verhandelingen Kon. Akademie Wetenschappen, Amsterdam, 37, 10, p. 819-825.
('Variation statistics method applied to a large collection of Schizoblastus from the Permian of Timor and some new anomalies of this genus'. Permian blastoids from Basleo and Niipol, W Timor)

Jell, P.A. (1999)- A monasterid starfish from the Permian of Timor. Mem. Queensland Museum, Brisbane, 43, 1, p. 340.
(Brief first description of two arms of small Permian starfish from Noil Tonino I, SE of Basleo, from Macurda collection)

Johnston, C.R. (1981)- A review of Timor tectonics with implications for the development of the Banda Arc. In: A.J. Barber & S. Wiryosujono (eds.) The geology and tectonics of Eastern Indonesia, Proc. CCOP-IOC SEATAR Working Group Mtg., Bandung 1979, Geol. Res. Dev. Centre (GRDC), Bandung, Spec. Publ. 2, p. 199-216.
(Australia- Timor collision started ~3Ma, but almost all continental rocks in Timor formed part of Banda forearc. Jurassic and older continental rocks of Timor have N Australian affinity, but probably rifted off in Late

Jurassic, collided with SE Asia subduction zone in Cretaceous and was reunited with Gondwanaland when Australian continent arrived at this subduction zone)

Johnston, C.R. & C.O. Bowin (1981)- Crustal reactions resulting from the mid-Pliocene to Recent continent island arc collision in the Timor region. BMR J. Australian Geol. Geophysics 6, p. 223-243.
(online at: www.ga.gov.au/corporate_data/81078/Jou1981_v6_n3_p223.pdf)
(DSDP-262 data suggest continental edge of Australia first entered subduction zone in Timor region at ~3 Ma. With map of position of pre-collisional continental margin of Australia)

Jonker, H.J.W. (1873)- Rapport van het voorloopig onderzoek naar de aanwezigheid van kopererts op het eiland Timor. Jaarboek Mijnwezen Nederlandsch-Indie 1873, 1, p. 157-186.
('Report of the preliminary investigation of presence of copper ore on Timor Island'. Earlier reports on presence of copper minerals (malachite, lazurite) in N coastal area of Timor could partly be confirmed, but nowhere in commercially significant quantities. Areas investigated in regions of Harneno and Beboki dominated by serpentinitic rock, Fialarang and Niti copper-bearing claystones, etc.)

Jouannic, C., C.H. Hoang, W.S. Hantoro & R.M. Delimon (1988)- Uplift rate of coral reef terraces in the area of Kupang, West Timor; preliminary results. Palaeogeogr. Palaeoclim. Palaeoecology 68, p. 259-272.
(In Kupang area seven uplifted Quaternary coral reef terraces. Fifth step at +44m dated at 152,000 yrs, giving mean uplift rate of 0.3 mm/yr since last interglacial; faster uplift rates in other parts of Timor)

Juliansyah, M.N. & R.D. Putrohari (2014)- Identifying the amount of uplifting of Timor Island using pressure data in Banli-1 well, Bonaparte Basin, southern Banda Arc. Proc. 43rd Ann. Conv. Indon. Assoc. Geol. (IAGI), Jakarta, PIT IAGI 2014-060, 5p.
(Banli-1 well drilled in 1993 in S edge of W Timor. Overpressure interval indicates uplift event of Timor. Depth of Jurassic on Timor Island 2296' higher than on Ashmore Platform. Minimum amount of uplift of Timor Island identified from difference between actual pressure data and hydrostatic pressure curve is ~1800', suggesting position of Timor Island prior to late uplift is already higher than Ashmore Platform of NW Australian margin)

Kadarusman, A., S. Maruyama, Y. Kaneko, T. Ota, A. Ishikawa, J. Sopaheluwakan & S. Omori (2010)- World's youngest blueschist belt from Leti Island in the non-volcanic Banda outer arc of Eastern Indonesia. Gondwana Research 18, 1, p. 189-204.
(Timor-Tanimbar non-volcanic outer Banda Arc with world's youngest 'A'-type high-P metamorphic belt, outcropping with different stages of evolution. Advanced domal uplift in Timor, still in first stage of tectonic extrusion on Kisar, Leti, Moa, Sermata and Laibobar. Metamorphics on Leti tectonically juxtaposed against overlying ultramafic rocks and underlying unmetamorphosed continental shelf sediments, bound by normal and reverse faults, respectively. Leti metapelites and metabasite units progressive metamorphic zones; highest grades in structurally intermediate levels. Protoliths of Leti metamorphics originally Permo-Triassic. Sediments and igneous rocks at margin of advancing Australian continent entered subduction zone immediately prior to commencement of Banda Arc-Australia collision in Pliocene. Burial reached 30-35 km. Slab-breakoff at depth in collision zone facilitated rapid uplift by wedge extrusion and active erosion during exhumation)

Kadarusman, A., S. Maruyama, Y. Kaneko, T. Tsujimori, T. Ohta & J. Sopaheluwakan (1997)- On-going exhumation of blueschist belt in the Timor-Tanimbar Region, Eastern Indonesia. Abstracts, Japan Earth and Planetary Science Joint Meeting 1997, p.

Kamptner, E. (1955)- Fossile Coccolithineen-Skelettreste aus Insulinde; eine mikropalaeontologische Untersuchung. Verhandelingen Kon. Nederl. Akademie Wetenschappen, Amsterdam, ser. 2, 50, 2, p. 1-105.
(online at: www.dwc.knaw.nl/DL/publications/PU00011530.pdf)
('Fossil coccolith skeletal remains from Indonesia: a micropaleontological investigation'. Study of coccolithophores from Jurassic-Cretaceous and Upper Tertiary marls of Timor and Roti, from same samples as studied by Tan Sin Hok 1927 and later also by Jafar 1975. Paleontological study without maps or stratigraphic context. Numerous new species)

Kaneko, Y., S. Maruyama, A. Kadarusman, T. Ota, M. Ishikawa, T. Tsujimori, A. Ishikawa & K. Okamoto (2007)- On-going orogeny in the outer-arc of the Timor-Tanimbar region, Eastern Indonesia. Gondwana Research 11, p. 218-223.
(Timor-Tanimbar one of youngest high P/T metamorphic belts in world. Deformation and metamorphic grade increase towards centre of 1 km thick crystalline belt. Metamorphics extruded as thin sheet between ophiolites and underlying shelf sediments. Central crystalline unit Barrovian-type overprint of high P/T metamorphics during wedge extrusion, and metamorphic grade pumpellyite-actinolite to upper amphibolite facies. Quaternary uplift of ~1260m in Timor in W, decreasing toward Tanimbar. Exhumation of metamorphics started in Late Miocene in W Timor, migrating/younging to E. Deep-seated high P/T metamorphic belt extruded into shallow levels, followed by doming. 'Mountain building' restricted to second stage. Quaternary uplift due to rebound of subducting continental crust due to oceanic slab break-off. Tanimbar not yet affected by later doming)

Kanmera, K. & K. Nakazawa (1973)- Permian- Triassic relationship and faunal changes in the eastern Tethys. In: Permian-Triassic systems and their mutual boundary. Mem. Canadian Petroleum Geol. 2, p. 100-119.
(Description of stratigraphy and faunal sequences of Upper Permian- Lower Triassic from sections in Japan, S China and Indochina. Timor 'allochthonous' shallow marine Asinepe Limestone close affinities to Asian facies and faunas; Audley-Charles et al. 1979)

Karig, D.E., A.J. Barber, T.R. Charlton, S. Klemperer & D.M. Hussong (1987)- Nature and distribution of deformation across the Banda Arc-Australian collision zone at Timor. Geol. Soc. America (GSA) Bull. 98, 1, p. 18-32.
(Profiles near Timor show Banda Arc-Australia collision zone similar to typical oceanic subduction system. Present deformation most intense at foot of Timor Trough inner slope. Deformation front discontinuously advancing S as new thrust slices develop in subducting Australian margin strata. Present deformation negligible in Savu fore-arc basin, N of Timor. Back-arc thrusting N of volcanic arc, but convergence minor compared with Timor Trough deformation. Along-strike variations in Timor Trough- Savu Basin deformation may be related to variable degree of involvement of Australian continental margin along arc)

Kato, M., K. Takeuchi, A. Hendarsyah & D. Sundari (1999)- On the occurrence of the Permian brachiopod genus *Leptodus* in Timor. Geol. Res. Dev. Centre (GRDC), Bandung, Seri Paleontologi 9, p. 43-51.
(Brachiopod Leptodus probably from Permian Maubisse Fm, now embedded in Tertiary clay, indicates Timor was in Tethyan faunal realm (but Kato et al. also quote Leptodus occurrence in W Australia; JTvG). Timor Permian marine faunas closer affinity to SE Asian Permian faunas than to Australian Gondwana)

Kaye, S.J. (1989)- The structure of eastern Indonesia: an approach via gravity and other geophysical methods. Ph.D. Thesis, University College, University of London, p. 1-239.
(online at: www.bandaarcgeophysics.co.uk/Thesis/Thesis-kaye.pdf)
(Study of tectonics of Timor and Tanimbar-Kai regions incorporating gravity data. With discussions of obducted ophiolite terrains and comparisons to PNG and Taiwan. Assumes most of material on Timor belongs on NW Australian margin, and prior to collision Timor region was probably promontory or plateau composed of sedimentary and volcanic units)

Keep, M., L. Barber & D. Haig (2009)- Deformation of the Cablac Mountain Range, East Timor: an overthrust stack derived from an Australian continental terrace. J. Asian Earth Sci. 35, 2, p. 150-166.
(Cablac Mountain Range in E Timor S-directed thrust stack of mainly Triassic- E Jurassic carbonates, in structural contact with underlying Lolotoi Fm metamorphics. Lolotoi Fm and overlying Gondwanan thrust stack structurally emplaced on M Eocene units to S. Cablac thrust stack bound to N by high-angle fault along which crush breccia with clasts from Gondwana Megasequence and Asian Banda Terrane. Previously Cablac Lst suggested to be massive E Miocene limestones in depositional contact with underlying units)

Keep, M., L. Beck & P. Bekkers (2005)- Complex modified thrust systems along the southern margin of East Timor. Australian Petrol. Prod. Explor. Assoc. (APPEA) J. 2005, p. 297-310.
(Study of Plio-Pleistocene accretionary wedge along S coast of East Timor)

Keep, M. & D.W. Haig (2010)- Deformation and exhumation in Timor: distinct stages of a young orogeny. Tectonophysics 483, p. 93-111.
(E Timor data suggest major break between deformed pre-collisional strata and relatively undeformed overlying deposits in Late Miocene (9.8-5.5 Ma). Three distinct phases of orogenic development: initial collision and emplacement of early nappes creating loading and diapirism (9.8-5.5 Ma), tectonic quiet interval (5.5 Ma- 4.5 Ma), which may represent time of locking of subduction system, and post 4.5 Ma uplift, unroofing and further diapirism in response to isostatic rebound. First emergence above sea level ~3.1 Ma))

Keep, M. & D.W. Haig (2010)- Timor collision: deformation and tectonic implications. 20th Australian Geological Convention, Canberra 2010, Geol. Soc. Australia, Abstracts 98, p. 205. *(Abstract only)*
(New biostratigraphic dating places collision between Australian Plate and Banda Arc at 10.9- 9.8Ma. Collision produced complex intercalation of thrust slices from Australian Plate and Banda Arc sides of plate boundary. Initial thrust emplacement between 9.8-5.5 Ma. Intercalation of Australian-derived material with material from Banda Terrane complicated by over-folding of Banda Terrane thrust slices. Young high-angle strike-slip faults control much of present-day topographic expression of island)

Kenyon, C.S. (1974)- Stratigraphy and sedimentology of the Late Miocene to Quaternary deposits of Timor. Ph.D. Thesis, University of London, p. 1-291. *(Unpublished)*
(Stratigraphy of W Timor includes late M Miocene- Quaternary (N15-N23) Viqueque group sediments above Bobonaro olistostrome. Viqueque group subdivided into 6 formations, 26 members. Several phases of uplift and subsidence. Paleogeographies showing uplifted area to N, deep water sediment transport to South)

(Zircon ages from Triassic Babulu Fm deep marine clastics in Fohorem area, Timor-Leste, Neoarchean-Triassic, with main age pulses Paleozoic- Triassic (329-256 Ma). Proterozoic major peak at 1878-1857 Ma, also at ~1560, 1750, 1830 Ma (results similar to Zobell 2007 data from Savu). Maximum deposition age indicated by youngest zircon age peak (~256-238 Ma) is post- early U Triassic. Babulu Fm in Fohorem area initiated as submarine fan lobe and represents distal Gondwana Sequence of Australian margin. Zircon age for M Permian trachyandesite in Maubisse Fm (270 ± 3 Ma= E Guadalupian))

Lakeman, R. (1950)- On the crinoid nature of *Timorocidaris sphaeracantha* Wanner. Proc. Kon. Nederl. Akademie Wetenschappen, Amsterdam, 53, 1, p. 100-108.
(Timorocidaris sphaeracantha one of most common fossils in Permian of Timor. Hemispherical fossil, here believed to be axillary primibranch of unknown poteriocrinoid, not an echinoid)

Lay, A., I. Graham, D. Cohen, J.M. Gonzalez-Jimenez, K. Privat, E. Belousova & S.J. Barnes, (2014)- Platinum Group Minerals in ophiolitic chromitites of Timor Leste. In: E.V. Anikina et al. (eds.) 12th Int. Platinum Symposium, Inst. Geology and Geochemistry UB RAS, Yekaterinburg, p. 179-180. *(Abstract)*
(online at: http://conf.uran.ru/12IPS/12%20IPS%20ABSTRACTS.pdf)
(Hili Manu peridotites in Manatuto District on N coast of Timor Leste, ~50km E of Dili with ultramafic rocks(serpentinised dunites, harzburgites and lherzolites associated with rare rodingites and gabbros) in two massifs, separated by amphibolite block. With chromitite bodies and Platinum-Group mineralisation. Preliminary PGM Re-Os ages from 0.05 Ga (Subao Highway) to 0.21 Ga (Kerogeol Hill))

Lay, A., I. Graham, D. Cohen, K. Privat, J.M. Gonzalez-Jimenez, E. Belousova & S.J. Barnes (2017)- Ophiolitic chromitites of Timor Leste: their composition, platinum group element geochemistry, mineralogy, and evolution. Canadian Mineralogist 55, 5, p. 875-908.
(Ultramafic rocks at Hili Manu, ~50 km E of Dili , two ultramafic massifs separated by amphibolite. Chromitite bodies at Hili Manu small lenses few m in size. Chromites both high-Cr and high-Al types. Platinum-group

minerals (laurite, etc.) as inclusions and in fractures in chromite or serpentinite matrix. Peridotite geochemistry and chemistry of chrome-spinels suggest formation of Hili Manu peridotite in upper mantle in supra-subduction zone setting, part of young oceanic lithosphere from Banda Arc)

Lelono, E.B. (2016)- Palynology of the Permian freshwater deposit in West Timor. J. Geologi Sumberdaya Mineral 17, 4, p. 231-239.
(online at: http://jgsm.geologi.esdm.go.id/index.php/JGSM/article/view/18/16)
(Permian Bisane Fm of W Timor dominated by calcareous sandstone with abundant marine crinoid fossils. Intercalation of non-calcareous dark shale-siltstone with papery structure, 5m thick, with Permian striate-bisaccate pollen, incl. Protohaploxypinus samoilovichii and other species (associated with Glossopteris flora), Striatopodocarpidites phaleratus, Pinuspollenites globosaccus, Lunatisporites pellucidus, etc. and lack marine dinoflagellates. Possibly syn-rift lacustrine deposit)

Lelono, E.B. (2017)- Pollen record of the Permian marine sediments from West Timor. Lemigas Scientific Contributions Oil and Gas 40, 2, p. 75-84.
(online at: http://journal.lemigas.esdm.go.id/ojs/index.php/SCOG/article/view/42/pdf)
(Permian calcareous shale and sandstone at 50m thick Lilana river outcrop (Bisane Fm) with moderate pollen recovery (mostly consists of striate and non-striate bisaccates as well as trilete monosaccates). Permian age taxa Protohaploxypinus samoilovichi, Lunatisporites pellucidus, Falcisporites australis, Plicatipollenites malabarensis and Cannanoropollis janakii. Common marine dinoflagellates Dapsilidium langii and Veryhachim reductum and abundant crinoid macrofossils confirm shallow marine paleoenvironment. Common Tasmanites green algae in lower part of section suggest potential hydrocarbon source rock)

Lelono, E.B. (2019)- The Gondwanan green alga *Tasmanites* sp. in the Permian lacustrine deposits of West Timor. Indonesian J. Geoscience 6, 3, p. 255-266.
(online at: http://ijog.bgl.esdm.go.id/index.php/IJOG/article/view/434/290)
(Permian lacustrine sediments of W Timor 5m thick non-calcareous black shale with papery structures and part of Bisane Fm. Rich but low diversity palynomorphs indicate non-marine environment. >80% of pollen assemblages green alga Tasmanites sp., also striate/ non-striate bisaccate pollen and trilete spores, indicating Permian age. Tasmanites believed to be source for tricyclic terpanes, a primary source of hydrocarbons)

Lelono, E.B., P. Bohemi, A. Bachtiar, P. Suandhi, B.H. Utomo, H. Ibadurrahman, M. Arifai, A. Yusliandi & Z. Lesmana (2016)- Paleozoic lacustrine sediment at West Timor and tectonic implication for Timor Island, new exploration concept of hydrocarbon. Proc. 40th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, IPA16-642-G, 12p.
(Discovery of 5m thick non-calcareous black shale with papery structure at Ajobaki Village, Fatunausus High, Kapan, Soe (in mud volcano?). Consisting of algae layered with sulphur content. With Late Permian(?) fresh water pollen species (incl. Permian Plicatipollenites malabarensis and P. janakii (=Cannanoropollis janakii?) and Triassic Protohaploxypinus samoilovichi and Falcisporites australis) and interpreted as lacustrine deposits. High maturity (Ro>0.9), TOC up to 24% (NB: Possibly Triassic bituminous shale?: Falcisporites australis, Cannanoropollis janakii, P. samoilovichi may occur in Late Permian but primarily Triassic markers. Little info on geological context of sample; JTvG))

Lelono, E.B., D. Kurniadi, K.D. Anggritya & Saidah (2017)- Palynological review of the Permian lacustrine sediment in the West Timor. Proc. Joint Conv. HAGI-IAGI-IAFMI-IATMI (JCM 2017), Malang, 6p.
(Palynology of new locality of 4m thick non-calcareous black 'paper shale' in central W Timor interpreted as Late Permian lacustrine deposit. High abundance but low diversity of palynomorphs. Tasmanites-green algae >80% of pollen assemblage; rest assemblage striate and non-striate bisaccate and trilete spore, characterising Permian age. Tasmanites blooms interpreted as lake supplied with meltwater from surrounding glaciers. Tasmanites algae potential hydrocarbon source (NB: Tasmanites commonly viewed as pelagic marine algae, common in higher latitudes? (e.g. Barentsz Sea M Triassic marine oil shales with Tasmanites blooms and common Daonella bivalves; Vigran et al. 2008; JTvG). No details on locality)

Lelono, E.B., L. Nugrahaningsih & D. Kurniadi (2016)- Permo-Triassic palynology of the West Timor. Scientific Contr. Oil and Gas, Lemigas, Jakarta, 39, 1, p. 1-13.
(online at: www.lemigas.esdm.go.id/public/publikasi/scientific/14778917121993082162.pdf)
(Bisane Fm sandstones-shales in W Timor outcrops with mica and abundant crinoids and up to 5m thick non-calcareous dark shale-siltstone with papery structure and rich in sulfur. Permo-Triassic ages indicated by striate-bisaccate pollen, incl. Protohaploxypinus samoilovichii, P. fuscus, P. goraiensis (= from Glossopteris plants), Striatopodocarpidites phaleratus, Pinuspollenites globosaccus, Lunatisporites pellucidus, also non-striate Falcisporites australis, Samaropollenites speciosus, etc. Trilete-monosaccate spores of Plicatipollenites malabarensis and Cannanoropollis janakii in non-calcareous shale samples Permian or older age. Marine dinoflagellates in calcareous samples (incl. Dapsilidinium langii, Dingodinium jurassicum) suggest marine influence, and not present in non-calcareous samples. Possibly new petroleum system in Paleozoic of W Timor? (NB: dinoflagellates include latest Triassic-Jurassic species?; JTvG))

Lelono, E.B., L. Nugrahaningsih, D. Kurniadi, P.A. Suandhi & B.H. Utomo (2016)- Palynological investigation of the Permian sediment in the on-shore West Timor. Proc. GEOSEA XIV and 45th Ann. Conv. Indon. Assoc. Geologists (IAGI) (GIC 2016), Bandung, p. 401-404.

(On discovery of second specimen of large blastoid Calycoblastus tricavatus Wanner from Lower Permian of Baun-Amarasi near Kupang, W Timor)

Major, J.R. (2011)- Pleistocene hinterland evolution of the active Banda Arc: surface uplift and neotectonic deformation recorded by coral terraces at Kisar, Indonesia *and* Hinterland emergence of the active Banda arc-continent collision: metamorphism, geochronology, and structure of the uplifted Kisar Atoll, Indonesia and related rocks of Timor. M.Sc. Thesis, Brigham Young University, Utah, p. 1-165.
(online at: http://scholarsarchive.byu.edu/cgi/viewcontent.cgi?article=3945&context=etd)
(Metamorphic rocks of Kisar island correlate with Aileu Metamorphic Complex of E Timor. Protoliths mostly psammitic with minor basaltic and felsic igneous material. Mafic meta-igneous rocks show rift affinities, likely related to rifting of Gondwana. Collision of N margin of Australia with Banda Arc in latest Miocene caused metamorphism of distal edge of continental margin rocks at depths of 25-30 km, followed by rapid uplift and exhumation. U-Pb analysis of detrital zircons show main populations of ~300 Ma and ~1850 Ma. Youngest grains are ~286/ 295 Ma in age (earliest Permian). Timing of metamorphism poorly constrained by previous studies; mica cooling age of 5.36 Ma reliable. Domal geometry expressed by pinnacle shape of island and by metamorphic foliations parallel to coastline, possibly caused by diapirism into hinge of active thrust anticline)

Major, J.R. & R. Harris (2009)- The tectonic evolution and regional significance of Kisar Island, Indonesia. Geol. Soc. America, Rocky Mount. Sect. 61st Ann. Mtg., May 2009, Paper 13-11. *(Abstract only)*

(Kisar Island, NE of Timor, emerges from small ridge in forearc suture zone 3 km deep. Consists of metamorphic rocks encircled by Quaternary uplifted coral terraces. Terraces gently warped and correlated to known sea-level highstands. Metamorphic rocks among youngest in world, range from phyllite to amphibolites)

Major, J.R., R.A. Harris, H. Chiang, C. Prasetyadi & C. Shen (2009)- Variation in deformational mechanisms in the Banda Arc: uplift and tectonic implications of Kisar, Indonesia. EOS Transactions AGU 90, 52, Fall Meet. Suppl., Abstract T33B-T1915. *(Abstract only)*

(Coral terrace ages yield surface uplift rate of ~0.5 m/ka for Kisar Island in hinterland of active Banda arc-continent collision. Based on this rate, Kisar first emerged from ocean as recently as ~450 ka. Uplifted terraces gently warped in E-W striking folds. Pinnacle shape of Kisar and protrusion of its metamorphic rocks through forearc basin sediments also suggest component of extrusion along shear zones or active doming)

(Short note reporting that large collections of macrofossils from Permian, etc., of Timor, originally kept in Amsterdam, Delft and Leiden, are now combined in Leiden Naturalis Museum)

Milsom, J. & M.G. Audley-Charles (1986)- Post-collisional isostatic readjustment in the southern Banda Arc. In: M.P. Coward & C. Ries (eds.) Collision tectonics, Geol. Soc. London, Spec. Publ. 19, p. 353-364.
(Timor area considerable departures from isostatic equilibrium suggested by gravity. In some cases isostatic anomalies accords well with observed vertical movement. In other areas, such as N Timor and inner (volcanic) arc, uplift where gravity data suggest there should be subsidence. Possible explanation is contribution to high gravity made by cold, dense subducted slab now sinking after rupture near continental margin. Ruptured sinking slab no longer exerts downward pull on overlying lithosphere, freed to rebound isostatically.)

Milsom, J. & A. Richardson (1976)- Implications of the occurrence of large gravity gradients in N Timor. Geologie en Mijnbouw 55, p. 175-178.
(online at: https://drive.google.com/open?id=0B7j8bPm9Cse0b3hDbTV1SUpySGs)
(Steep gravity gradient along N coast of Timor suggests dense rocks rise close to surface, and analogies can be drawn with large anomalies associated with ophiolitic thrusts in New Guinea and New Caledonia, where high gravity anomalies caused by concealed roots of exposed ultramafic masses. Timor may well be built up of series of thrust slices resting ultimately on continental basement)

('The Timor Expedition and its paleontological results'. Summarizing results of expeditions by Molengraaff and Wanner 1911-1912 and Jonker in 1915. Collected well-preserved, rich, mainly shallow marine Permian faunas, particularly rich in crinoids and blastoids, and also ammonites. Also thin Triassic and Jurassic deep sea deposits on Timor and Roti with manganese nodules and radiolarians, formed in very deep water, very far from landmasses. Upper Triassic faunas remarkably similar to rocks from Alps and Himalyas)

Molengraaff, G.A.F. (1920)- Mangaanknollen in Mesozoische diepzee-afzettingen van Nederlandsch Timor. Verslagen Kon. Akademie Wetenschappen, Amsterdam, Wis- Natuurk. Afd., 29, p. 677-692.
('Manganese nodules in Mesozoic deep-sea deposits of Dutch Timor, etc.. Dutch version of Molengraaff (1921))

Molengraaff, G.A.F. (1921)- On manganese nodules in Mesozoic deep-sea deposits of Dutch Timor with a preliminary communication on fossils of Cretaceous age in those deposits by L.F. de Beaufort. Proc. Kon. Nederl. Akademie Wetenschappen, Amsterdam, 23, 7, p. 997-1012.
(Online at: www.dwc.knaw.nl/DL/publications/PU00014760.pdf)
(Several meters of deep-marine red clays with manganese nodules sampled by Jonker in 1916 from Noil Tobee river, 4.5 km ENE of Niki-Niki. Red clays conformably overlie thin-bedded Late Triassic limestone with Halobia. Partly dissolved Elasmobranchii shark teeth similar to English Chalk species, suggesting Cretaceous age (not clear if contact is tectonic or represents Jurassic hiatus in condensed deep water series; JTvG))

Morgan, R.F. (2015)- Three new species of *Deltoblastus* Fay from the Permian of Timor. PLoS One 10, 6, e0127727, p. 1-9.
(online at: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4465186/)
(Review of15 species of blastoid genus Deltoblastus, with introduction of 3 new species, based on material from Basleo, etc. (now in Waco and London museum collections))

Muhammad, F., I G.B.E. Sucipta & M.G Sagara (2017)- Origin and tectonic emplacement of mylonitized peridotite in Hili Manu Area, Timor Leste. Proc. Joint Conv. HAGI-IAGI-IAFMI-IATMI (JCM 2017), Malang, 6p.
(Hili Manu peridotite body in Timor Leste is spinel lherzolite peridotite with mylonitic structures. Geothermobarometry from exsolution lamellae of pyroxenes indicate peridotite formed at 1190°C and 8.5 kb (850 MPa). Rocks mylonitized at 964- 1092°C and 4.9-5.7 kb (490-570 MPa). Metamorphism of underlying Permian Aileu Fm increases toward base of peridotite; sole metamorphism during peridotite emplacement)

Mulder, E. & J.W.M. Jagt (2019)- *Globidens(?) timorensis* E. Von Huene, 1935: not a durophagous mosasaur, but an enigmatic Triassic ichthyosaur. Neues Jahrbuch Geologie Palaontologie, Abhandl. 293, 1, p. 107-116.
(Three isolated sauropsid tooth crowns described in 1935 by E. von Huene from Timor, tentatively attributed them to new species of Late Cretaceous mosasaurid Globidens(?) timorensis not Late Cretaceous mosasaurs, but Triassic ichthyosaur)

Mulhadiono & B. Simbolon (1988)- Preliminary account of the petroleum potential of Timor Island. Proc. 17th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 89-110.
(Overview of Timor geology, accepting Asian origin of Mutis-Palelo, Maubisse and N Coast thrust complexes. Main deformation phase between Late Eocene- earliest Miocene. 21 wells drilled in E Timor, Metai 1 and Taci with minor oil tests. Various source formations present, but reservoir quality may be poor)

Muller, S. (1844)- Bijdragen tot de kennis van Timor en enige andere naburige eilanden. In: Temminck, C.J. (ed.) Verhandelingen over de natuurlijke geschiedenis der Nederlandsche overzeesche bezittingen door de leden der Natuurkundige Commissie in Indie en andere schrijvers, 1, Land en Volkenkunde, Leiden, p. 129-320.
(online at: https://ia802907.us.archive.org/2/items/verhandelingeno00temm/verhandelingeno00temm.pdf)
('Contributions to the knowledge of Timor and some neighboring islands'. Early naturalist descriptions of West Papua from Muller's 1828-1830 Triton Expedition)

Munasri (1998)- Early Cretaceous radiolarian biostratigraphy of the Nakfunu Formation, the Kolbano area, West Timor, Indonesia. Ph.D. Thesis, University of Tsukuba, Japan, No. 1869, p. *(Unpublished)*
(Berriasian-Aptian cherts and mudstone from Kolbano area of SW Timor contain radiolarians from two different climates: southern high latitudes and tropics)

Munasri & A.H. Harsolumakso (2020)- Late Cretaceous radiolarians from the Noni Formation, West Timor, Indonesia. Berita Sedimentologi 45, p. 5-18.
(online at: https://www.iagi.or.id/fosi/files/2020/05/FOSI_BeritaSedimentologi_BS45-May_2020.pdf)

(Late Cretaceous (Cenomanian-Turonian) radiolarian fauna from chert sample of Noni Fm in Miomaffo District, which is generally viewed as part of the allochthonous 'Banda Terrane'. Radiolarian fauna close resemblance to S Sulawesi and very different from age-equivalentfaunas in 'autochthonous' southern foldbelts of West Timor (Kolbano) and Timor Leste (Viqueque))

Munasri & K. Sashida (1999)- Tethyan and non-Tethyan Early Cretaceous radiolarian fauna from West Timor, Indonesia. In: H. Darman & F.H. Sidi (eds.) Tectonics and sedimentation of Indonesia, FOSI-IAGI-ITB Regional Seminar to commemorate 50th anniversary of Van Bemmelen's Geology of Indonesia, Bandung 1999, p. 88-91.
(Radiolaria in E Cretaceous Nakfunu Fm of Kolbano accretionary complex of southern W Timor indicate trend of increasing number of Tethyan species, reflecting N-ward motion of N Australian continental slope: (1) Berriasian- E Valanginian mainly non-Tethyan taxa of Parvicingula, Crytocapsa, etc. (Circum-Arctic cold-water faunas); (2-3) Late Valanginian- E Barremian both Tethyan and non-Tethyan taxa; (4) E Aptian Tethyan taxa only (Dictyomitra pseudoscalaris, Stichomitra spp., etc.))

Munasri & K. Sashida (2018)- Tethyan and non-Tethyan Early Cretaceous radiolarian faunas from West Timor, Indonesia: paleogeographic and tectonic significance. Earth Evolution Sciences (University of Tsukuba) 12, p. 3-12.
(Abundant and well-preserved E Cretaceous radiolaria in calcilutites and shales of Nakfunu Fm, Kolbano area, southern W Timor, in part of accretionary complex. Radiolarian faunas similar to ODP Leg 123- Site 785 from Argo Abyssal Plain. Four assemblages of Berriasian- E Aptian age, with trend from non-Tethyan to Tethyan affinities in progressively younger strata. Frequent and random repetition of radiolarian assemblages reflect imbrication of beds. Faunas derived from S paleolatitude origin, influenced by Circum-Antarctic current)

Nakazawa, K. & Y. Bando (1968)- Lower and Middle Triassic ammonites from Portuguese Timor (Paleontological study of Portuguese Timor 4). Mem. Fac. Science, Kyoto University, Ser. 4, Geol. Mineralogy, 34, 2, p. 83-114.
(online: http://repository.kulib.kyoto-u.ac.jp/dspace/bitstream/2433/186548/1/mfskugm%20034002_083.pdf)
(First report on E-M Triassic (U Scythian- Lw Anisian) ammonites from Timor Leste. from cephalopod limestones in 3 localities: (1) in N (W of Manatuto; area of mixed Triassic and Permian 'Fatu Limestones', SE of area of amphibolites/ serpentinite); (2) in S (N and SE of Pualaca= near Nogami 1963 Permian fusulinid locality; with M and Late Triassic 'Fatu limestones') and (3) in E (Tutuala; Late Triassic). Sixteen species incl. Dieneroceras dieneri, Anasibirites multiformis, Meekoceras spp., Procarnites, Leiophyllites timorensis, etc. With listings of associated conodonts)

Nguyen, N., B. Duffy, J. Shulmeister & M. Quigley (2012)- Rapid Pliocene uplift of Timor. Geology 41, 2, p. 179-182.
(Palynology of 34 samples of Pliocene turbidites-marls from type section of 200m thick Viqueque Fm of E Timor. From ~4.5- 3 Ma palynomorphs mainly from Australia and New Guinea (Casuarina, Eucalyptus, etc.), with increasing swamp and mangrove elements from emerging proto-Timor. After ~3.1 Ma pollen and charcoal track rapid uplift of Timor with progressive appearance of montane and dry, lee-side floristic elements. E-M Pliocene uplift rates of 0.5-0.6 mm/yr increased to 2-5 mm/yr in latest Pliocene)

Nicoll, R.S. (1999)- Triassic conodont faunas from Australia and Timor. In: H. Yin & J. Tong (eds.) Proc. Int. Conf. Pangea and the Paleozoic- Mesozoic transition, Wuhan 1999, China Univ. Geoscience Press, p. 140-141.
(Abstract only)
(Conodonts at various horizons in Timor Triassic similar to Australia NW shelf margin)

Nicoll, R.S. & C.B. Foster (1998)- Revised biostratigraphic (conodont-palynomorph) zonation of the Triassic of Western and northwestern Australia and Timor. In: P.G. & R.R. Purcell (eds.) The sedimentary basins of Western Australia 2. Proc. Petroleum Expl. Soc. Australia (PESA) Symposium, Perth, 2, p. 129-139.
(Studies of relationships between conodont faunas and spore-pollen and dinocyst palynofloras from W Australian margin and Timor have revised calibration of Australian Triassic palynomorph zones and stage terminology. Wombat-Timor Trough (newly defined) is axis of sedimentation on NW Shelf in Triassic)

Niermann, H.T. (1975)- Polycoeliidae aus dem Oberperm von Basleo auf Timor. Munstersche Forsch. Geol. und Palaont. 37, p. 131-225.
(Taxonomic revision of Polycoeliidae family of solitary rugose corals from lower Upper Permian of Basleo, Timor, based on 490 specimens collected by Ehrat in 1927, and mainly building on work of Gerth (1921) and Koker (1924). 25 species, 13 new species, 10 new subspecies. No stratigraphy or locality information)

Nieuwenkamp, W.G.J. (1919)- Bezoek aan eenige slijkvulkanen op Kambang en Semaoe (West-Timor). Tijdschrift Kon. Nederlands Aardrijkskundig Genootschap 36, p. 488-492.
(online at: https://resolver.kb.nl/resolve?urn=MMUBA13:001665001:pdf)
('Visit to some active mud volcanoes on Kambang and Semau, West Timor'. Over 150m high composite mud volcanoes. Nothing on rock inclusions)

Niko, S., T. Nishida & K. Nakazawa (2000)- Orthoconic cephalopods from the Lower Permian Atahoc Formation in East Timor. Paleontological Research, Japan, 4, 2, p. 83-88.
(online at: www.palaeo-soc-japan.jp/download/PR/PR4-2.pdf)
(Three species of orthoconic cephalopods described from Lower Permian Atahoc Fm in Cribas area, E Timor (Mooreoceras sp., Atahococeras timorense), signifying Late Paleozoic non-ammonoid cephalopod fauna at N margin of Gondwana near Sakmarian-Artinskian boundary)

Nogami, Y. (1963)- Fusulinids from Portuguese Timor (Palaeontological study of Portuguese Timor 1). Mem. College of Science, Kyoto University, Series Geol. Min., B30, 2, p. 59-68.
(Four Early Permian fusulinid species (incl. Schwagerina nakazawae n.sp., Codonofusiella weberi, Parafusulina) described from limestone lens in basic tuffs in Fatu Auveon near Pualaca in C East Timor and N of Hato-Builico in W part of E Timor. Samples collected by Nakazawa in 1961)

Nogami, Y. (1968)- Trias-Conodonten von Timor, Malaysien und Japan (Palaeontological study of Portuguese Timor 5). Mem. Fac. Science, Kyoto University, Ser. Geol. Min. 34, 2, p. 115-136.
('Triassic conodonts from Timor, Malaysia and Japan'. Seven conodont faunas recognized in Triassic of Malaysia, Timor and Japan. Conodonts from Timor from samples collected by Nakazawa of ammonoid-bearing limestone of Lacon River, Manatuto District, Timor Leste, mainly Middle Triassic age. Includes description of new species Gondolella timorensis (now assigned to Chiosella; JTvG), a worldwide marker species for Lower Anisian, base of M Triassic. Malaysian material from Kodiang Lst probably all Late Triassic in age (specimen of Pl. 8, fig. 8 assigned to late Carnian Epigondolella primitia by Mosher (1973))

Nutzel, A. (2007)- Cephalopoden (Ammoniten, Nautiliden und *Aulacoceras*) aus der Trias von Timor (Indonesien). Freunde Bayerischen StaatsSammlungen Palaont. Hist. Geol., Munchen, Jahresbericht 2006 und Mitteilungen 35, p. 32-34.

Orchard, M.J. (1994)- Conodont biochronology around the Early-Middle Triassic boundary: new data from North America, Oman and Timor. Memoires de Geologie (Lausanne) 22, p. 105-114.
(online at: www.unil.ch/)
(Includes discussion of Triassic conodonts in matrix around ammonites from 'Hallstatt-facies' limestone block of Timor, from which Tozer (1994) described ammonites. Common Chiosella timorensis and fewer Gladiogondolella tethydis, suggest E Anisian (M Triassic) age, simillar to assemblages from Oman and Chios (Base C. timorensis (Nogami) appears to be reliable conodont marker for E-M Triassic boundary; JTvG))

Ormeling, F.J. (1957)- The Timor problem: a geographical interpretation of an underdeveloped island. Wolters, Groningen, 284p.

(General geographic study of Timor)

Osberger, R. (1954)- Contribution to the geology of Timor. IV. Notes on Plio-Pleistocene corals of Timor. Indonesian J. Natural Science 110, p. 80-82.
(On corals from uplifted Plio-Pleistocene reef terraces near Lalan Asu, collected by De Waard expedition. Material generally poorly preserved)

Ota, T. & Y. Kaneko (2010)- Blueschists, eclogites, and subduction zone tectonics: insights from a review of Late Miocene blueschists and eclogites, and related young high-pressure metamorphic rocks. Gondwana Research 18, 1, p. 167-188.
(Review of formation and exhumation of Late Miocene blueschist and eclogite belts, including Timor-Tanimbar blueschist belt and world's youngest coesite- bearing eclogite in PNG)

Pakuckas, C. & G. von Arthaber (1928)- Nachtrag zur Mittel- und Obertriadischen Fauna der Ammonoidea trachyostraca C. Dieners aus Timor. In: H.A. Brouwer (ed.) 2e Nederlandsche Timor-Expeditie VI, Jaarboek Mijnwezen Nederlandsch-Indie 56 (1927), Verhandelingen 2, p. 143-218.
(Addendum to Diener (1922) work on thousands of M- Late Triassic ammonites, by student and associate of C. Diener in Vienna. Ammonites collected from loose blocks in W Timor by 1916 Jonker expedition. Anisian-Carnian and probable Rhaetian assemblages, most of them similar to 'Halstatter Facies' of Mediterranean Province)

Panjaitan, S. & S. Hutubessy (1997)- Analisis tektonik berdasarkan paleomagnetik di daerah Timor-Timur. J. Geologi Sumberdaya Mineral, 7, 70, p. 19-27.
('Tectonic analysis of East Timor area based on paleomagnetic data'. Declination/ inclination results from 'allochthonous' and 'parautochthonous' outcrops mainly along traverse S of Dili rather variable: (1) Permian Aileu Fm 6°/-31° and 126°/48° (interpreted as deposited at latitude 29°N), (2) Late Permian Cribas Fm 150°/ 50 (deposited at 30.7°N), (3) Permian- Triassic Maubisse Fm 220°/44° (deposited at 25.7°N), (4) Late Triassic Aitutu Fm 295°/-54°(deposited at 34.5°S) and (5) Jurassic Wailuli Fm 18°/-22° (deposited at 11.4°S). In Late Triassic Timor was still close to Australian continent, in Jurassic already started to make move to N)

Panjaitan, S. & S. Hutubessy (2004)- Pembentukan formasi batuan di Pulau Timor ditinjau dari data paleomagnet dan gayaberat. J. Sumber Daya Geologi 14, 1 (145), p. 55-68.
('Formation of Timor island rock formations as observed from magnetic and gravity data'. Contribution to Asian vs. Australian origin of Timor rock units: Permian Aileu Fm formed at paleolatitude 48º N, Cribas Fm at ~31º N, Maubisse Fm at 25º N, all far N of equator and at S edge of Asian continent. Plate moved S since Triassic to form thrust sheets in Timor Island. Triassic Aitutu Fm formed at ~34º S and Jurassic Wailuli Fm at ~11º S, both far S of equator and part of Australian continent. Collision between Allochthon and Para-Autochthon rocks seen on 150 mgal negative Bouguer anomaly, in which Australian continent plate with density of 3.0 gr/cm³ subducted and depressed under Banda Sea plate)

Park, S.I., H.J. Koh, S.W.Kim, Y.H. Kihm (2014)- The occurrence and origin of a syn-collisional melange in Timor. Economic Environmental Geol. 47, 1, p. 1-15.
(online at: http://ocean.kisti.re.kr/downfile/volume/kseeg/JOHGB2/2014/v47n1/JOHGB2_2014_v47n1_1.pdf)
(In Korean, with English abstract. Bobonaro melange syn-collisional melanges formed during collision between Australian continental margin and Banda arc. In Suai area melange matrix of unmetamorphosed red-green clay with scaly texture, with allochthonous blocks. Melange classified into 1) diapiric; 2) tectonic; and 3) broken formation. Melange intruded all pre-collisional units including lower Australian margin unit (Gondwana megasequence) and Banda arc unit. Interpreted to be mainly formed as diapiric melange originated from Gondwana megasequence)

Park, S.I., S. Kwon & S.W. Kim (2014)- Evidence for the Jurassic arc volcanism of the Lolotoi complex, Timor: tectonic implications. J. Asian Earth Sci. 95, p. 254-265.
(SHRIMP U-Pb zircon ages from two andesitic metavolcanic rocks in Lolotoi complex, Timor Leste, yield permissible range of M Jurassic extrusion from 177-174 Ma (~late E Jurassic; Toarcian). Inherited grains age

cluster of 242 ± 4 Ma and oldest grain of 1848 Ma. Basaltic-andesitic metavolcanics products of prolonged oceanic crust and arc magmatism, respectively. Parts of Banda forearc basement are pieces of allochthonous oceanic basalts and Jurassic arc-related andesites accreted to Sundaland during closure of Mesotethys, and incorporated later into Great Indonesian Volcanic Arc system along SE margin of Sundaland (NB: suggests Lolotoi Metamorphics younger than 'Gondwana sequence' of Timor; JTvG))

Partoyo, E., B. Hermanto & S. Bachri (1995)- Geological map of the Baucau Quadrangle, East Timor, 1:250,000. Geol. Res. Dev. Centre (GRDC), Bandung.

Riding, R. & S. Barkham (1999)- Temperate water *Shamovella* from the Lower Permian of West Timor, Indonesia. Alcheringa 23, p. 21-29.
(Problematic sponge-like calcareous fossil generally called Tubiphytes is common in Permian- Triassic reefs. Here called Shamovella obscura and locally abundant in Late Sakmarian Hoeniti Mb of Maubisse Fm near Bisnain, eastern W Timor, associated with brachiopods of temperate water affinity)

Riedel, W.R. (1953)- Mesozoic and late Tertiary Radiolaria of Rotti. J. Paleontology 27, 6, p. 805-813.
(Re-examination of the radiolarian fauna described by Tan Sin Hok (1927) from calcareous sediments from Bebalain, Rotti Island. Fauna previously assigned probably Pliocene age, but contains reworked(?) Cretaceous forms (Spongosaturnalis, Stylosphaera, Tricolocapsa, Stichomitra etc.). Radiolaria from nearby locality probably of Pliocene- Pleistocene age))

Ritsema, L. (1951)- Description de quelques Alveolines de Timor: resultat dûune elaboration de la methode des courbe dôindice de Reichel. Proc. Kon. Nederl. Akademie Wetenschappen, Amsterdam, B54, 2, p. 174-182.
('Description of some alveolinids from Timor'. Eocene Alveolina limestones collected by Van West in Miomaffo region, W Timor, contain five species)

Ritsema, A.R. (1956)- Gravity measurements on Timor Island. Indonesian J. Natural Science (Majalah Ilmu Alam untuk Indonesia) 112, 2, p. 171-174.
(Highest positive gravity anomalies in area of young volcanic rocks on N coast. Strip of small negative values in Central basin probably related to Nikiniki fault. Good correspondence of anomalies with geologic units)

Ritsema, A.R. (1956)- Two gravity profiles across Timor Island. Verhandelingen Kon. Nederl. Geologisch Mijnbouwkundig Genootschap, Geol. Serie 16 (Gedenkboek Brouwer), p. 380-385.
(Two N-S gravity profiles across W Timor: Kupang- Buan and Ocussi- Kolbano, Surveyed in 1954. All Bouguer anomalies of Timor island are positive, with highest values near N coast. Lowest and possibly negative Bouguer anomaly in narrow strip around Nikiniki and Central Depression)

Robba, E., S. Sartono, D. Violanti & E. Erba (1989)- Early Pleistocene gastropods from Timor (Indonesia). Memorie Scienze Geol., Padova, 41, p. 61-113.
(Rich marine gastropod fauna (56 species) and foraminifera from E Pleistocene marl (Batuputih Fm) from Oe Sapi creek, Tinu, 1 km NE of Atambua town, W Timor, collected during 1954-1957 ITB expeditions. Lyellian percentage of living species 56%. Associated with rich marine foraminiferal fauna (85% planktonics, incl. Globorotalia tosaensis, but no G. truncatulinoides). Common Neogloboquadrina dutertrei and presence of

Neogloboquadrina pachyderma suggesting upwelling of cold currents. Interpreted to be deposited in 150-250m of water, influenced by cold currents)

Rocha, A. Tavares & M. de Lourdes Ubaldo (1964)- Foraminiferos do Terciario Superior e do Quaternario da provincia Portuguesa de Timor. Mem. Junta de Investigacoes do Ultramar 51, Lisboa, p. 1-180.
('Foraminifera of the Late Tertiary and Quaternary of the Portuguese province of Timor'; in Portuguese)

Rocha, A. Tavares & M. de Lourdes Ubaldo (1964)- Contribuicao para o estudo foraminiferos do Terciario superior de Timor. Garcia de Orta: Revista da Junta de Investigacoes do Ultramar 12, 1, p. 153-158.
('Contribution the the study Late Tertiary foraminifera of Timor')

Romariz, C. & J. de Azeredo Leme (1967)- Subsidios para a petrografia timorense. Calcarios de fato. Garcia de Orta: Revista da Junta de Investigacoes do Ultramar 15, 1, p. 111-122.
('Contributions to Timor petrography: Fatu limestones')

Roniewicz, E. & G.D. Stanley (2009)- *Noriphyllia*, a new Tethyan Late Triassic coral genus (Scleractinia). Palaeont. Zeitschrift, DOI 10.1007/s12542-009-0030-8, p. 467-478.
(Noriphyllia new genus of solitary coral, with two new E Norian and one Carnian species. Widely distributed in E Norian reef facies of Tethys region and occurs in Carnian of Timor. Noriphyllia monatutoensis n.sp. type locality is Saututun, Manatuto, Timor Leste, in Carnian limestone (exotic boulders?) in Babulu Fm)

Roniewicz, E., G.D. Stanley, F. Da Costa Monteiro & J.A. Grant-Mackie (2005)- Late Triassic (Carnian) corals from Timor-Leste (East Timor): their identity, setting and biogeography. Alcheringa 26, 2, p. 287-303.
(Four coral taxa from Late Triassic limestone in Babulu Fm sst-shale sequence at Manatuto, E Timor N coast (incl. Paravolzei, Craspedophyllia, Margarosmilia confluens). Affinities to Carnian faunas from Italy. Previously, only Norian corals known from Timor Triassic. Carnian faunas help confirm paleogeographic affinities with W Tethys (NB: stratigraphically above Norian dinoflagellate Wanneria listeri (Da Costa Monteiro 2003 in Charlton et al. (2009), suggesting possible Norian age for these corals?; JTvG))

Roosmawati, N. (2005)- Long-term surface uplift history of the active Banda Arc-continent collision: depth and age analysis of foraminifera from Rote and Savu Islands, Indonesia. M Sc. Thesis, Brigham Young University, p. 1-120.
(online at: http://scholarsarchive.byu.edu/cgi/viewcontent.cgi?article=1558&context=etd.)
(Foraminifera documentation of Pliocene age and deep water facies of Batu Putih Fm marls on Rote and Savu)

Roosmawati, N. & R. Harris (2009)- Surface uplift history of the incipient Banda arc-continent collision: geology and synorogenic foraminifera of Rote and Savu Islands, Indonesia. Tectonophysics 479, p. 95-110.
(Synorogenic pelagic units of Rote and Savu show rapid uplift of Banda arc-continent collision in past 1.8 Myr. Synorogenic Batu Putih Fm unconformably over accreted units, aged N18- N22 (5.6- 1.0 Ma), deposited at depths of ~3000m and unconformably overlain by uplifted coral terraces. Highest coral terraces in Savu 300m above sea level; in Roti up to 200m. Collision of Australian margin with Banda Arc earlier in Timor, propagated W to Roti (initial stages of accretionary wedge emergence). Collision of Scott Plateau propagated SE from Sumba (2-3 Ma) to Savu (1.0- 0.5 Ma), then to Roti (0.2 Ma). Average uplift of Batu Putih Fm pelagics in past 2 Myr in Roti and Savu ~1.5 and 2.3 mm/yr. Rise of islands is clogging Indo-Pacific seaway)

Roosmawati, N., R.A. Harris, H. Nugroho et al. (2004)- Long-term surface uplift history of the active Banda arc-continent collision: depth and age analysis of foraminifera from Rote and Savu Islands, Indonesia. Abstract Geol. Soc. America(GSA) 2004 Denver Ann. Mtg., Paper No. 152-15.

(Synorogenic deposits in W Roti outcrops are of Late Pliocene age (zone N21; 3.1-1.8 Ma) with paleowater depths deeper than 2500m. Banda arc-continent collision arrived in Roti after ~3 Ma, possibly later in Savu)

Rose, G. (1994)- Late Triassic and Early Jurassic radiolarians from Timor, Eastern Indonesia. Ph.D. Thesis, University of London, p. 1-384. *(Unpublished)*
(Rich Upper Carnian- Rhaetian radiolarian faunas from Aitutu and Wai Luli Fms in River Meto sections, central W Timor. Additional material collected from presumed Triassic on Buton, Leti, Moa, Babar, but no radiolarians recovered. Timor Triassic radiolarian assemblages differ from European Tethys, Philippines and Japanese assemblages. E Jurassic assemblages closer to Japan than other areas. Apparent Late Rhaetian- E Sinemurian time gap at Triassic-Jurassic boundary (Carter 2007: Rhaetian radiolarian faunas from W Timor with some cosmopolitan taxa, but others have stronger affinities with those in Japan and Philippines)

Rosidi, H.M.D., S. Tjokosapoetro, S. Gafoer & K. Suwitodirdjo (1979)- Geologic map of the Kupang-Atambua Quadrangles, Timor, 1: 250,000. Geol. Res. Dev. Center, Bandung.
(1:250,000 surface geology of westernmost Timor, and Roti and Savu islands; see also 2nd edition- 1996))

Rothpletz, A. (1891)- The Permian, Triassic and Jurassic formations in the East Indian Archipelago (Timor and Rotti). American Naturalist 25, p. 959-962.
(Early summary of 'new' Timor- Roti fossils, based on examination of Wichmann collection. Timor Late Paleozoic fossils here regarded as Permian in age, not Carboniferous as previously thought)

Darman & F.H. Sidi (eds.) Proc. Tectonics and sedimentation of Indonesia seminar, Bandung 1999, Indon. Sedim. Forum Spec. Publ. (Abstracts volume), 1, p. 88-91.

Sashida, K., Munasri, S. Adachi & Y. Kamata (1999)- Middle Jurassic radiolarian fauna from Rotti Island, Indonesia. J. Asian Earth Sci. 17, 4, p. 561-572.
(Folded 'Wai Luli Fm' calcareous shale near Baa at NW coast of Roti with Late Bajocian- Early Bathonian low-latitude 'Tethyan' radiolarian assemblage of Tricolocapsa plicarum Zone. Believed to be deposited in deep ocean, far from land. In same areas also Late Triassic and Early Cretaceous thin-bedded limestones with radiolarians Assemblage of 15 species of 7 genera, dominated by Tricolocapsa spp., Stichocapsa spp., Archaeodictyomitra spp. and Cyrtocapsa. New species Tricolocapsa multispinosa and T. matsuokai)

Sashida, K., Munasri, S. Adachi & K. Ueno (1996)- Early Cretaceous radiolarian faunas from the Nunleo area in southwest Timor, Indonesia. In: B. Ratanasthien & S.L. Rieb (eds.) Proc. Int. Symposium on Geology and Environment, Chiang Mai, Thailand, p. 223. *(Abstract only)*
(online at: http://library.dmr.go.th/Document/Proceedings-Yearbooks/M_1/1996/)
(Well-preserved E Cretaceous radiolaria assemblages in abyssal calcilutite of Nunleo area of Kolbano Complex, SW Timor: (1) late Berriasian- Valanginian, with non-Tethyan general Parvicingula, Eucyrtis, Eusyringium and Spongocapsula; (similar to NE Indian Ocean faunas); (2) Hauterivian- Barremian Dibolachras tytthopora assemblage, with Tethyan and non-Tethyan species)

Sawyer, R.K., K. Sani & S. Brown (1993)- The stratigraphy and sedimentology of West Timor, Indonesia. Proc. 22nd Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 1, p. 533-574.
(Amoseas W Timor fieldwork, stratigraphy overview. Three main packages in Permian-Neogene outcrops on West Timor: (1) E Permian- E Pliocene sediments deposited on Gondwana and Australian continental- oceanic crust (Kekneno and Kolbano Sequences), (2) Neogene syn- and post-orogenic sediments (Viqueque Sequence) and (3) Lower Cretaceous-Neogene volcanic arc and forearc basin sediments of Banda Terrane. Age of Oe Baat Fm glauconitic sandstone of Kekneno seriesof SW Timor revised to Tithonian- Berriasian (equivalent of Flamingo Gp of NW Shelf, Buya Fm of Sula, Woniwogi Fm of W Papua, etc.))

Schneider, C.F.A. (1863)- Bijdrage tot de geologische kennis van Timor. Natuurkundig Tijdschrift Nederlandsch-Indie 25, p. 87-107.
('Contribution to the geological knowledge of Timor'; in Dutch. One of first geological descriptions of Timor (Kupang area), by German physician Schneider. Young coral limestone terraces, oolitic limestones, manganese beds, dark clays green sandstone-marl with brachiopods (Spririfer, Orthis, Terebratula, etc.), believed to be of Jurassic age. Also near Bakoelnassi bright-colored marls and sandstones with Gervillea and Trigonia, crinoid limestones, Cretaceous chalk, basaltic diorite near Tabeno, etc. According to locals skeleton of giant fish was found near Ikafoti (= Ichthyosaurus?; JTvG). No maps or figures)

Schubert, R. (1915)- Die Foraminiferen des jungeren Palaozoikums von Timor. Palaontologie von Timor, Schweizerbart, Stuttgart, 2, 3, p. 47-60.

('The foraminifera of the younger Paleozoic of Timor'. First paper on Timor Permian fusulinids and smaller foraminifera from many localities, collected by Wanner, Molengraaff and Weber expeditions (no maps). (Thought to be Late Carboniferous age, but placed in Early Permian by later workers. Four species described. Parafusulina wanneri is type species of Monodiexodina wanneri; JTvG)

Schubert, R. (1915)- Uber Foraminiferengesteine der Insel Letti. Jaarboek Mijnwezen Nederlandsch Oost-Indie 43 (1914), Verhandelingen 1, p. 169-187.
('On the foraminifera-bearing rocks of the island of Leti'. Abundant, rel. large elongate Permian fusulinids in loose limestone blocks, described as Doliolina lepida var. lettensis (Thompson 1948: small fauna of verbeekinids described here from Leti is different from Timor faunas). Also Upper Cretaceous Globotruncana linneana and E Miocene Lepidocyclina and Heterostegina (= Spiroclypeus; JTvG))

Shimizu, D. (1966)- Permian brachiopod fossils of Timor (Palaeontological study of Portuguese Timor 3). Memoirs College Science, Kyoto University, Ser. B, Geol. Min., 32, 4, p. 401-427.
(17 brachiopod species from E Timor localities suggest Early Permian age. At some localities in part of autochthonous complex of reddish or purplish brown tuffaceous shale; in others associated with purplish tuffaceous, occasionally argillaceous limestones and shales (characterized as 'Bitauni fauna by Waterhouse (1973)= Artinskian?; JTvG))

Sieverts, H. (1933)- *Jouannetia cumingi* (Sowerby) aus den Pliocan von Timor nebst Bemerkungen uber andere arten dieser Gattung. Neues Jahrbuch Mineral. Geol. Palaontologie, Beilage Band 71, p. 267-307.
('Jouannetia cumingi from the Pliocene of Timor, with remarks on other species of this genus'. Detailed description of pholadid boring bivalve from Late Pliocene- Pleistocene raised coral reefs, now at 500-700m above sea level, in Basleo region of W Timor. This near-spherical shell species is known from Recent coral reefs of Indo-Pacific, drilling into coral bodies)

Simons, A.L. (1939)- Geological investigations in N.E. Netherlands Timor. Ph.D. Thesis University of Amsterdam, p. 1-110. *(Unpublished)*
(online at: https://resolver.kb.nl/resolve?urn=MMKB21:038250000:pdf)
(NE part of W Timor (S of Atapupu, W of Atambua) common serpentinites and associated amphibolite schists and undeformed Tertiary andesitic volcanics (incl. pillow lavas), overlain by Late Miocene and/or Pliocene 'Batu Putih' Globigerina marls with siliceous tuff interbeds near N coast. Permo-Triassic flysch, bathyal Mesozoic 'Sonnebait series' and massive Permian and Triassic 'Fatoe complex' limestones in S. Fig. 17 suggests serpentinites and diabase overlie Triassic Kekneno clastics, in turn overlain by Permo-Triassic Sonnebait and Fatoe limestones. Triassic sandstones rich in micas, tourmaline, zircon and garnet and derived from crystalline schists. Late Tertiary marly limestones with hornblende, augite, hyperstene, pointing to erosion of young volcanic deposits. Permian and Triassic in 3 different facies-tectonic types: Kekneno, Sonnebait and Fatoe. Folded pelagic Late Jurassic and Late Cretaceous sediments also present. Tectonic complexity and incomplete exposures prohibit stratigraphic colums or detailed cross-sections)

Simons, A.L. (1940)- Geological investigations in N.E. Netherlands Timor. In: H.A. Brouwer (ed.) Geological Expedition of the University of Amsterdam to the Lesser Sunda Islands 1937, 1, Noord Hollandsche Publ. Co., Amsterdam, p. 107-214.
(Same as Simons (1939))

Sinaga, S.H., R. Adiarsa, F. Alĉayubie, D. Aulia, I.A. Arindra, I.R. Sialagan & H. Tanjung (2011)- Geological observation of Soe, Kuanfatu, Kualin area and its implications for petroleum system of West Timor. Proc. 35th Ann. Conv. Indon. Petroleum Assoc. (IPA), Jakarta, 16p.
(Outcrop observations on W Timor. Some samples analyzed for geochemistry. Highest TOC 0.75-1.0% in Triassic-Jurassic Aitutu and Wailuli Fms)

Siwindono, T., B. Manumayoso, D. Priambodo & R.P. Yudantoro (1997)- Mesozoic exploration target in East Timor, Indonesia. 15th World Petroleum Congress, Beijing 1997, p. *(Abstract only*
(Suai-Betano block in S part of Timor Leste. Permian- E Miocene generally in thrust structures, post-collision M Miocene-Pleistocene sediment deposited in suspended basin pond. Bobonaro Fm melange deposits in many areas of Suai-Betano block, with exotic blocks of Permian age. Some nappe structures present. Between 1914-1974 23 exploration wells drilled in Timor Basin. Cota Taci-1 tested 200 BO/D and Matal-1 180 BO/D from Bobonaro exotic blocks. Suailoro-1 oil show (also in Bobonaro exotic block?). Many oil seeps in Mesozoic reservoirs: Fatuberliu oil seep (Wailuli Fm sst) and Bemetane oil seep (Waibua Fm sst))

Smith, J.P. (1927)- Permian ammonoids of Timor. In: H.A. Brouwer (ed.) 2e Nederlandsche Timor-Expeditie 1916, IV, Jaarboek Mijnwezen Nederlandsch-Indie 55 (1926), Verhandelingen 1, p. 1-58.
(Ammonoid material from 1916 Jonker expedition to Timor. Richest Permian ammonoid fauna in world, in both species and abundance. Especially rich in Cyclolobidae and Medlicottiidae and rel. poor in Ceratitoidea. Successive Permian age faunas: (1) E Permian Somohole (common Marathonites, Gastrioceras, Paralegoceras, Pronorites), Bitauni (Perrinites, Agathiceras sundaicum, Paralegoceras spp.) and Basleo (with Waagenoceras, increase in Haloritidae); (2) Late Permian? Amarassi/ Ajer Mati fauna (still with Cyclolobus). Latest Permian faunas not seen in Timor)

Sopaheluwakan, J. (1990)- Ophiolite obduction in the Mutis complex, Timor, eastern Indonesia. An example of inverted, isobaric, medium-high pressure metamorphism. Ph.D. Thesis Free University, Amsterdam, VU University Press, p. 1-226.
(Mutis and Miomaffo metamorphic complexes have inverted metamorphic gradients and formed by obduction of hot, young ophiolite over oceanic rocks in Early Cretaceous. K-Ar age of 37 Ma corresponds to cooling below 300° C of terrane after mild reheating, up from depth of 5-6 km, suggestings major uplift in Late Eocene. This is then interpreted as Eocene collision onto Australian craton (possibly Sundaland margin event?; JTvG))

Sopaheluwakan, J. (1991)- The Mutis metamorphic complex of Timor: a new view on the origin and its regional consequences. Proc. 20th Ann. Conv. Indon. Assoc. Geol. (IAGI), Jakarta, p. 301-315.
(Mutis and Miomaffo complexes metamorphics in W Timor formed from MOR Basalt and continent-derived greywacke. Structurally overlain by peridotite, with inverted metamorphic gradient (granulite near base of peridotite through amphibolite to greenschist- blueschist at base of sequence. Interpeted as metamorphic sole below ophiolite, formed during intra-oceanic thrusting. Crustal extension terminated Mutis Complex deformation. K-Ar age of ~37 Ma of mica in metapelite reflects Late Eocene cooling/uplift)

Sopaheluwakan, J., H. Helmers, S. Tjokrosapoetro & E. Surya Nila (1989)- Medium pressure metamorphism with inverted thermal gradient associated with ophiolite nappe emplacement in Timor. In: J.E. van Hinte et al. (eds.) Proc. Snellius II Symposium, Jakarta 1987, Netherlands J. Sea Research 24, p. 333-343.
(Mutis and Miomaffo Massifs metamorphosed pelitic and basic rocks associated with serpentinized peridotites. Decrease in metamorphic grades below and away from peridotites, with Mutis Massif slightly higher-grade metamorphism than Miomaffo. P-T-D plots of Mutis samples yield T gradient of 300 °C/·km in 1 km thick metamorphite below basal peridotite. Invertedly zoned metamorphites and other indications suggest Mutis and Miomaffo Massifs represent metamorphic aureoles below ophiolite slab)

Sorauf, J.E. (1978)- Original structure and composition of Permian rugose and Triassic scleractinian corals. Palaeontology 21, 2, p. 321-339.
(Study of Permian solitary coral structure based on exceptionally well-preserved material in Wanner collection from Guadalupian of Basleo 23 locality, SW Timor (Polycoelia angusta, Timorophyllum wanneri, Lophophyllidium spinosum))

Spencer, C.J., R.A. Harris & J.R. Major (2016)- Provenance of Permian-Triassic Gondwana Sequence units accreted to the Banda Arc in the Timor region: constraints from zircon U-Pb and Hf isotopes. Gondwana Research 38, p. 28-39.
(online at: http://geology.byu.edu/Home/sites/default/files/2015_spencer_et_al_-_gr_-_timor_upbhf.pdf)
(Zircons from Permian-Triassic 'Gondwana sequence' of Timor yield age distributions with large age peaks at 230-400 Ma and 1750-1900 Ma, similar to zircon age spectra from NE Australia and similar to terranes of N Tibet and Malaysia. 1750-1900 Ma zircon peak also very common in other terranes in SE Asia. Hf analysis of zircon from Aileu Complex in Timor and Kisar shows bimodal distribution at ~300 Ma, probably from bimodal magmatic event, and ties to presence of interbedded Permian mafic and felsic rocks. Similar rock types and isotopic signatures also in Permian-Triassic igneous units throughout Cimmerian continental block. Permian-Triassic of Timor region fill syn-rift intra-cratonic basins that successfully rifted in Jurassic to form NW margin of Australia. This margin first entered Sunda Trench in Timor region at ~7-8 Ma, causing Permo-Triassic rocks to accrete to edge of Asian Plate and emerge in young Banda collision zone)

Springer, F. (1918)- A new species of fossil *Pentacrinus* from the East Indies. In: Nederlandsche Timor-expeditie, II. Jaarboek Mijnwezen Nederlandsch Oost-Indie 45 (1916), Verhandelingen 1, p. 59-64.

Standley, C.E. & R.A. Harris (2006)- Banda forearc metamorphic rocks accreted to the Australian continental margin in Timor: detailed analysis of the Lolotoi Complex of East Timor. EOS Transactions AGU, 87, 52, Fall Mtg. Suppl. *(Abstract only)*

(E Timor Lolotoi Complex part of group of thin metamorphic klippe, detached from Banda forearc and accreted to NW Australian margin during Late Miocene-Present arc-continent collision. Metamorphic protolith compositions similar to overlying unmetamorphosed tholeiitic basalt and andesite with oceanic arc affinities, and turbidites conglomerates and limestone (=also same as underlying rock?; JTvG). Dominant structure low-angle folding/thrusting to SE. Metamorphic terrain in thrust contact with underlying Gondwana sequence rocks. Mostly unmetamorphosed volcanic and sedimentary cover units found locally in fault contact on edges of the klippen. Ar/Ar ages from amphibolite in W Timor yield ages of 34-39 Ma, interpreted as metamorphism age. Lolotoi Complex part of eastern Great Indonesian Arc, which collapsed in Eocene, incorporated into Banda Arc in Miocene, and accreted to Australian margin in Pliocene- Present)

Standley, C.E. & R.A. Harris (2009)- Tectonic evolution of forearc nappes of the active Banda arc-continent collision: origin, age, metamorphic history and structure of the Lolotoi Complex, East Timor. Tectonophysics 479, 1-2, p. 66-94.
(online at: http://geology.byu.edu/home/sites/default/files/2009-lolotoi-cmplx.pdf)
(Lolotoi metamorphic complex of E Timor part of Banda forearc, metamorphosed and exhumed in Eocene and accreted to NW Australian continental margin in Late Miocene-Present. Greenschist, graphitic phyllite, quartz-mica schist, amphibolite and pelitic schist dominant metamorphics. Protoliths tholeiitic basalt and basaltic andesite with mixed MORB-oceanic arc affinities. Metapelite schist mostly metasedimentary units with volcanic arc provenance. Peak metamorphism at ~45.4 Ma indicated by Lu-Hf analyses of garnet. Detrital zircon U/Pb age spikes at 663, 120 and 87 Ma, typical of Great Indonesian Arc, distinct from Australian affinity units and indicating deposition and metamorphism after 87 Ma. Deformation phases: 1-4 pre-Oligocene, 5 and 6 related to latest Miocene- Pliocene nappe emplacement deformation. Lolotoi Complex in thrust contact with underlying Gondwana Sequence rocks. 'Asian' volcanic and sedimentary cover units mostly in normal fault contact with metamorphic rocks. Lolotoi Complex of Timor Leste correlative with Mutis Complex of W Timor, both part of Banda Terrane and dispersed fragments of E Great Indonesian Arc)

(Same as Tappenbeck, 1939)

Tate, G. (2014)- Structural deformation, exhumation and uplift of the Timor fold-thrust belt. Ph.D. Thesis, Princeton University, p. 1-251.
(online at: http://dataspace.princeton.edu/jspui/handle/88435/dsp01bk128d120)
(Thermochronology and micropaleontology reveal extreme heterogeneity in uplift and exhumation across Timor fold-thrust belt. Before synorogenic basins experienced uplift from >1 km below sea level at 3.4-3.0 Ma, other areas a few 10's of km away were emergent and exhuming rapidly. Balanced cross-sections document at least 326-362 km of shortening of Timor since at least 7.3-7.8 Ma, and 215-229 km of buoyant Australian continental margin subducted below Banda forearc)

Tate, G., N. McQuarrie, R.R. Bakker, D.J.J.van Hinsbergen & R.A. Harris (2010)- Active arc-continent accretion in Timor-Leste: new structural mapping and quantification of continental subduction. AGU 2010 Fall Meeting, San Francisco, Abstract T51A1996T, 1p. *(Abstract only)*
(New mapping in Timor-Leste provided view of structural repetition of 'Australian' continental sedimentary units below overriding Banda Arc material. Transect Laclo-Barique exposes deep erosional level, showing 3 regional NNE-striking thrust faults with ~3 km spacing, repeating Aitutu-Cribas stratigraphy. Jurassic Wailuli shales and Bobonaro melange act as upper decollement between this duplex and Lolotoi metamorphic basement of Banda Arc. New balanced structural cross-section produces minimum shortening of 320km)

Tate, G.W., N. McQuarrie, D.J.J. Hinsbergen, R.R. Bakker, R. Harris & H. Jiang (2015)- Australia going down under: quantifying continental subduction during arc-continent accretion in Timor-Leste. Geosphere 11, 6, p. 1860-1883.
(online at: http://www.pitt.edu/~nmcq/Tate_etal_2015_geosphere.pdf)
(Timor island is uplifted accretionary complex of collision of Banda arc with Australian continental margin. Duplexing of 2-km-thick Australian continental strata built majority of structural elevation of Timor orogen. Balanced cross sections suggest 326-362 km of shortening across Timor and 215-229 km of subduction of continental lithosphere below Banda forearc, showing considerable amounts of continental lithosphere can be subducted while accreting only thin section of uppermost crust. Continental subduction may have been favorable because of fast subduction rates and old oceanic crust at Australian margin)

Tate, G.W., N. McQuarrie, D.J.J. Hinsbergen, R.R. Bakker, R. Harris, S. Willett, P.W. Reiners, M.G. Fellin, M. Ganerod & J.W. Zachariasse (2014)- Resolving spatial heterogeneities in exhumation and surface uplift in Timor-Leste: constraints on deformation processes in young orogens. Tectonics 33, 6, p. 1089-1112.
(online at: http://onlinelibrary.wiley.com/doi/10.1002/2013TC003436/epdf)
(In Timor-Leste exhumed metamorphic rocks and piggyback deepwater synorogenic basins only 10's of km apart. Foraminifera in two deepwater synorogenic basins suggest basin uplift from depths of 1-2 km to 350-1000m between 3.35 and 1.88 Ma. Thermochronologic sampling in mountains between these basins: (1) reset age of ~7.13 Ma in Aileu high-grade belt suggests ~9-16 km of exhumation since that time; (2) zircon (U-Th)/He samples reset ages in Aileu Complex 4.4- 1.5 Ma, suggesting exhumation rates of 1-3 mm/yr with 2.7-7.8 km of exhumation since these ages; (3) Apatite (U-Th)/He ages in Gondwana Sequence 5.5- 1.4 Ma, suggesting 1-2 km of exhumation. Distinct increase in amount of exhumation in E Timor, from ~1-2 km in south to 3-6 km in North. Variability in surface uplift and exhumation possibly caused by ongoing subsurface duplexing driven by subduction and underplating of Australian continental crust)

Tate, G.W., N. McQuarrie, H. Tiranda, D.J.J. Hinsbergen, R. Harris, W.J. Zachariasse, M.G. Fellin, P.W. Reiners & S.D. Willet (2017)- Reconciling regional continuity with local variability in structure, uplift and exhumation of the Timor orogen. Gondwana Research 49, p. 364-386.
(New constraints on history of uplift, exhumation and shortening of W Timor. Foreland thrust stack of Jurassic-Miocene Australian margin strata and hinterland antiformal stack of Permo-Triassic Australian continental units duplexed below Banda Arc lithosphere. Piggyback Central Basin with deepwater synorogenic deposition from 5.57-5.53 Ma, uplift from lower-m bathyal depths at 3.35-2.58 Ma, and uplift from m-u bathyal at 2.58-1.30 Ma. Hinterland Permo-Triassic with apatite (U-Th)/He ages of 0.33-2.76 Ma, apatite FT ages of 2.19-3.53 Ma. Youngest or most reset in center of antiformal stack. Minimum of 300km of shortening including 210km of Australian continental subduction below Banda forearc. Timor-Leste similar timing of collision, etc.)

('Microblastus new genus and other new Permian blastoids from Timor'. In German. New species of blastoids from the Brouwer/ University of Amsterdam Timor collection)

Van Gorsel, J.T. (2012)- Ophiolite obduction on Leti Island, as described by Molengraaff and Brouwer (1915): implications for age and genesis of metamorphic complexes in the Outer Banda Arc, Eastern Indonesia. Berita Sedimentologi 24, p. 24-38.
(online at: www.iagi.or.id/fosi/files/2012/07/FOSI_BeritaSedimentologi_BS-24_July2012_S1.pdf)
(Descriptions of geology of Leti Island, NE of Timor by Molengraaff et al. (1915) suggest 'ophiolite obduction', (metamorphism of continental crustal material below ultrabasic mantle material in subduction zone). Folded E-M Permian sediments and basic volcanics in S of island gradually increase in metamorphic grade towards serpentinite massif in N. Serpentinite massif is overlain by Latest Oligocene shallow marine limestone with reworked serpentinite and metamorphics, suggesting metamorphism/ophiolite obduction on Leti island took place in post-Early Permian (therefore not Australian continental crust basement) but before latest Oligocene (i.e. too old to be connected with Late Neogene Banda arc- NW Australian continent collision). Metamorphic complexes on Timor and other islands of Outer Banda Arc may all have similar origin, possibly representing single, extensive Cretaceous-age collisional/ subduction zone, formed along Sundaland margin)

Van Marle, L.J. (1991)- Late Cenozoic palaeobathymetry and geohistory analysis of Central West Timor, Eastern Indonesia. Marine Petroleum Geol. 8, 1, p. 22-34.
(W Timor Central Basin with ~550m or more Mid-Pliocene- E Pleistocene deep marine clastics over E Pliocene pelagic calcilutites ('Batu Putih Fm'). E Pliocene paleo water depth probably ~2000m. Two uplift episodes(1) 2.4- 1.6 Ma, corresponding to arrival of Australian continental slope in subduction system; (2) Late Pleistocene- Recent larger uplift of 1500-2000m, reflecting arrival of Australian continental shelf at Outer Banda Arc thrust belt)

Van Voorthuysen, J.H. (1940)- Geologische Untersuchungen im Distrikt Amfoan (Nordwest Timor). In: H.A. Brouwer (ed.) Geological Expedition of the University of Amsterdam to the Lesser Sunda Islands 1937, 2, Noord Hollandsche Publ. Co., Amsterdam, p. 345-367.
('Geological investigations in the Amfoan District, NW Timor'. Reports a.o. common dark grey Eocene limestone with Nummulites, unconformable on crystalline schists of Mosu and Nefoneu (incl. Eocene conglomerate with rounded schist and volcanic clasts), closely associated with widespread Eocene andesitic

volcanics. Also blocks of Lower Miocene reefal limestone with Spiroclypeus and Miogypsina, always found in proximity to crystalline schists, and with clasts of schists and volcanics)

Van West, F.P. (1941)- Geological investigations in the Miomaffo Region, Netherlands Timor. Ph.D. Thesis University of Amsterdam, p. 1-130. *(Unpublished)*
(Miomaffo Massif of W Timor structurally complex area, with 3 tectonic units: (1) 'Schist-Palelo Complex' of amphibolite-dominated metamorphics associated with ultrabasic lherzolites, serpentinites, gabbros, etc., overlain by Cretaceous 'Lower Palelo' radiolarian cherts, U Cretaceous U Palelo greywackes-volcanoclastics with pebbles of schists and serpentinite, E-M Eocene Alveolina-Nummulites limestones associated with volcanics, Late Eocene Pellatispira limestones without volcanics, unconformably overlain by E Miocene limestones with Spiroclypeus and Miogypsina (with basal conglomerate with metamorphics, etc.), Globigerina limestone and increasing volcanic rocks upsection (Schist-'Palelo' stratigraphy resembles that of SE Kalimantan, SW Sulawesi, Sumba); (2) 'Fatu Complex' U Triassic reefal-oolitic limestones, some rich in Norian brachiopod Misolia aspera (with conglomeratic beds with igneous rocks); (3) 'Sonnebait Series' Cretaceous pelagic Globotruncana limestones and radiolarian cherts. Young Tertiary Globigerina limestones and tuffs unconformable over all older formations. Large overhrusts formed in pre-Miocene time, with mountain-building forces peaking in Oligocene, but fault deformation continuing to recent time)

Van West, F.P. (1941)- Geological investigations in the Miomaffo Region, Netherlands Timor. In: H.A. Brouwer (ed.) Geological expedition of the University of Amsterdam to the Lesser Sunda Islands in the eastern part of the Netherlands East Indies 1937, III, p. 1-131.
(Same as Van West (1941) above)

Villeneuve, M., H. Bellon, R. Martini, A. Harsolumakso & J.J. Cornee (2013)- West Timor: a key for the eastern Indonesian geodynamic evolution. Bull. Soc. Geologique France 184, 6, p. 569-582.
(W Timor not simple accretionary prism, but five superimposed structural units. Present-day structure result of three main tectonic events in Late Oligocene, Late E Pliocene and Late Pliocene-E Pleistocene. Geodynamic evolution: (1) block detached from Gondwana (unit 2) and drifted to Asiatic margin until Late Oligocene when it collided with Asiatic active margin (unit 3); (2) New block formed by units 2 and 3 drifted S in Miocene- E Pliocene until collision with Australian margin in Late E Pliocene; (3) Australian and Timor blocks moved together to NNE in Late Pliocene until collision with Banda fore-arc (unit 4); (5) In Pleistocene Timor island capped by 'autochthon' (unit 5) and (5) Quaternary? N thrusting of Banda volcanic arc over S Banda basin. Timor key area for building this geodynamical scenario of Indonesia)

Villeneuve, M., J.J. Cornee, A. Harsolumakso, R. Martini & L. Zaninetti (2005)- Revision stratigraphique de l'Ile de Timor (Indonesie orientale). Eclogae Geol. Helvetiae 98, 2, p. 297-310.
(online at: https://www.e-periodica.ch/digbib/view?pid=egh-001:2005:98316)
('Stratigraphic revision of Timor island'; in French. Many stratigraphic scales proposed for Timor due to tectonic complexity and facies variability. Timor comprises 6 units, linked to episodes of geological history. Evolution starts with Jurassic break-up of block from Gondwana (para-allochthonous unit), followed by Oligo-Miocene collision with Asian volcanic arc (allochthonous and sub-autochthonous units). By Late Miocene this assemblage of blocks separated from Asia during S Banda Sea opening (sub-autochthonous unit), then collided with N Australian margin in M Pliocene (Australian platform and Kolbano Group). Since then Timor Island part of Australian N margin).

Villeneuve, M., J.J. Cornee, R. Martini & L. Zaninetti (2004)- Nouvelle hypothese sur l'origine des formations geologiques de l'ile de Timor (Sud-Est Asiatique). Comptes Rendus Geoscience 336, 16, p. 1511-1520.
(Stratigraphy/ tectonics suggest Timor and S Sulawesi part of same continental block. Main deformation on Timor and Sulawesi is Oligocene. Timor separated in Late Miocene during opening of S Banda Basin and became part of Late Miocene arc that collided with Australia at end of E Pliocene, 3.5 Ma)

Villeneuve, M., A.H. Harsolumakso, J.J. Cornee & H. Bellon (1999)- Structure of West Timor (East Indonesia) along a north-south cross section. Geologie Mediterraneenne 26, p. 127-142.

(Structural transect of C part of W Timor suggests tow main tectonic events: (1) Oligocene thrusting of allochton units over Australian continental margin; (2) E Pliocene collision between Banda island arc and previous Timor forearc units, and responsible for present imbricated structures. Two extensional periods: Late Oligocene or earliest Miocena and Late Pliocene)

Vinassa de Regny, P. (1915)- Triadische Algen, Spongien, Anthozoen und Bryozoen aus Timor. Palaontologie von Timor, Schweizerbart, Stuttgart, 4, 8, p. 75-118.
(Late Triassic algae (Solenopora), sponges (Molengraaffia regularis, Steinmannia), corals (incl. species of Thecosmilia, Isastraea, Montlivaltia), pachyporidae (Lovcenipora), calcareous algae (Solenopora triasina = Parachaetes according to Flugel 1975), stromatoporidae (Stromatoporidium) and bryozoa, mainly from reefal 'Fatu Limestones' from westernmost Timor and Pualaca area, E Timor (Nine coral species in common with alpine Zlambachschichten; Diener 1916 (=Rhaetian; JTvG))

Vita-Finzi, C. & S. Hidayat (1991)- Holocene uplift in West Timor. J. Southeast Asian Earth Sci. 6, 3-4, p. 387-393.
(Holocene uplift rates <0.3mm/yr, i.e. much lower than Late Pliocene rates, suggesting rapid, but short-lived uplift of Timor in Late Pliocene)
